## 1 EXECUTIVE SUMMARY

The system-wide traffic operation and safety study of the Maine Turnpike includes an assessment of both current and future operating conditions of all interchanges, mainline sections, ramps, and toll plazas on the Turnpike between Kittery and Augusta. The study also includes an assessment of safety for all mainline sections, ramps, toll plazas, and intersections of local roads with Turnpike ramps.

The study is intended to present a broad look at safety and capacity needs on the Turnpike over the next 30 years. The purpose of the study is to provide information on needed capital improvements to help guide the Authority in the drafting of the 30-Year Capital Plan.

The parameters presented within the study include:

- A summary of current design hour traffic volumes (2011) for each mainline and ramp segment between Kittery and Augusta. Design hour volumes are the $30^{\text {th }}$ highest hour traffic volumes of a year.
- A forecast of future design hour traffic volumes at 10,20 , and 30 year horizons using applicable peak hour traffic growth rates and available forecasts.
- A highway and interchange capacity analyses for existing 10,20 , and 30 year design hour traffic volumes for mainline and ramps.
- A toll plaza operational analysis for existing, 10,20 , and 30 year design hour traffic volumes at each existing toll plaza location.
- An analysis of crash data from the most recent three year period for which data are available (2009-2011) along the Turnpike from Kittery to Augusta using data from the Maine Department of Transportation (MaineDOT).
- An analysis of Park and Ride lots adjacent to the Turnpike
- An evaluation of speeds from Exits 80-102
- Information from municipalities adjacent to the Turnpike regarding short or long term transportation improvements or problem areas

The study identifies the approximate timeframe and costs for needed capacity and safety improvements on the Turnpike. While other programs and/or policies might be developed to help address safety and capacity, including alternative transportation methods, this report provides information on when these issues are expected to arise and also provides basic estimates for the engineering and construction costs of adding these improvements to the highway.

Maine's Sensible Transportation Policy Act requires transportation agencies to identify and analyze alternatives to widening roadways in order to achieve capacity and safety needs. These alternatives have not been identified as part of this evaluation, however, will be done as a separate planning effort when necessary.

## CAPACITY IMPROVEMENTS

Capacity improvements, presented in Table 1-1, are based on the results of capacity analyses performed as part of the study. Included in Table 1-1 are possible future improvements, an approximate time table of when the improvements will become necessary, and an estimate of the forecasted construction costs. The costs have been forecasted to the year that construction is
proposed to begin. To summarize for budgeting purposes Table 1-1 combines the cost of all projects proposed to begin in the same year.

Table 1-1 - Cost of Proposed Improvements by Year

| Year | Total Forecasted <br> Cost | Location of Proposed Improvement |
| :--- | :--- | :--- |
| $2017^{1}$ | $\$ 2,996,700$ | NH State Line to Kittery Exit 2 - NB Mainline |
| 2018 | $\$ 3,617,500$ | Exit 36 Saco - Toll Lanes and NB On-ramp |
| 2021 | $\$ 2,423,000$ | Exit 36 Saco - NB Off Ramp |
| $2022^{1}$ | $\$ 7,962,600$ | NH State Line to Kittery Exit 2 - SB Mainline and Exit 2 SB-On-ramp |
| 2023 | $\$ 1,366,200$ | Exit 44 I-295 Scarborough SB On-Ramp |
| 2025 | $\$ 16,058,000$ | Jetport to Westbrook - NB Mainline |
| 2030 | $\$ 3,360,000$ | Exit 36 Saco - SB Off Ramp |
| 2031 | $\$ 25,062,900$ | Kittery Exit 2 to York - NB Mainline and Biddeford NB on-ramp |
| 2034 | $\$ 50,366,500$ | I-295 Scarborough to Jetport - NB Mainline <br> and Exit 32 Biddeford - SB off-ramp |
| 2035 | $\$ 26,446,000$ | Kittery Exit 2 to York - SB Mainline |
| 2037 | $\$ 21,880,000$ | I-295 Scarborough to Rand Rd - SB Mainline |
| 2038 | $\$ 2,838,100$ | Exit 36 Saco - SB On Ramp |

${ }^{1}$ Traffic between Exits 0-7 is constrained by the Piscataqua River Bridge. Peak hour northbound traffic will not reach forecasted levels due to the traffic capacity constraint of the bridge. Conversely, peak hour traffic southbound will not benefit from widening if the capacity of the bridge is less than the mainline (i.e. if the bridge is not widened). Because of capacity issues, coordination with the New Hampshire Department of Transportation will be needed in the near future.

In additions, three toll plazas (Biddeford, Scarborough, and Gray) were found to operate at over 75\% capacity and lie in close proximity to a local signalized intersection. Operations at these plazas should be monitored to ensure that the toll plaza operations don't interfere with the flow of traffic on local roads. It will also be important to monitor development in order to assess impact fees when necessary. This will be particularly important at Biddeford and Gray ${ }^{1}$, because these plazas will be operating at $80-90 \%$ capacity during peak periods. Periodic surges at these plazas could result in temporary interference with the local roads.

## HIGH CRASH LOCATIONS

The safety analysis for this study determined if there are locations with a high crash history; determined if there are measures that can be taken to alleviate the number of crashes; and examined the current safety practices of the Authority. All mainline miles, interchanges, ramps and toll plazas on the Maine Turnpike as well as adjacent intersections to the Turnpike were analyzed for this study. As a result of the analysis, improvements were suggested to improve high crash locations. The suggested improvements are the following:

- Advanced overhead signing for the York interchange on the southbound approach to the interchange.
- Modifying the acceleration lane at Wells to I-95 northbound from a taper to a parallel ramp
- A pavement sensor in the northbound lanes just north of the Wells interchange
- A pavement sensor in the southbound lanes north of Mayall Road in New Gloucester

[^0]- Deer crossing warning signs at Mile 71 north of Shaker Hill
- Sonic Nap Alert Patterns (SNAPS) on the shoulder of the southbound off-ramp in Wells
- Changes to guide signs at Exit 25 southbound off-ramp
- Overhead lane use signs at Exit 48 off-ramps right after the toll plaza

## PARK AND RIDE LOTS

All of the park and ride lots owned by the Authority were found to be utilized at a rate of less than $75 \%$ of available capacity for every year of the last three years with exceptions of the lots at Gray and Lewiston. The Gray Interchange is currently being studied. Possible relocation of the park and ride lot is part of that study. A new interchange in Lewiston is currently in the 30 -year plan. Due to the re-design of the Exit 80interchange, a larger, single, relocated, park and ride lot is being built and is scheduled to be open in late fall 2012.

## SPEED EVALUATION

Before a decision is made on maintaining or increasing the speed limit, the horizontal and vertical alignment should be evaluated. However, the evaluation did not find a design criteria and corresponding existing condition that prevents the speed limit from being raised in the section of roadway from Exit 80-102.

## OFF SYSTEM NEEDS

The Authority took a proactive approach to identify proposed projects that could adversely affect various aspects of Turnpike operations. The Authority obtained a list of current traffic movement permits, issued by MaineDOT for planned developments in the communities along the Turnpike corridor. The Authority also reviewed MaineDOT's State Transportation Improvement Program (STIP), for projects that may affect the turnpikes operations. Additionally, the Authority sent a letter to communities and Metropolitan Planning Organizations (MPO's) along the Turnpike corridor requesting information regarding existing reports or studies identifying short or long term transportation improvements or problem areas that are adjacent to the Turnpike. The following information received may impact the timeline for capacity improvements.

- Additional traffic generated by the proposed Technology Park will impact Turnpike traffic at and near Exit 47
- The proposed Stroudwater Place Development will also impact Turnpike traffic at and near Exit 47
- The cities of Saco and Scarborough are considering a study that will evaluate traffic congestion in their respective communities.
- Proposed developments along the Haigis Parkway will likely increase traffic volumes at or near Exit 42

A point of considerable interest, which arose during the research for this study, is the possible need for improvements that would involve the need for advanced planning with MaineDOT and local municipalities. These include, but are not limited to:

- Capacity needs on the Piscataqua River Bridge (also includes New Hampshire Department of Transportation)
- Study of traffic congestion in Saco
- Possible improvements to intersections adjacent to the Turnpike in Kittery, Wells, Westbrook, and Biddeford

## OTHER STUDIES

Outside of the course of this study, specific projects and issues have been identified that are being analyzed separately. The results of these studies could influence the timeline for capacity improvements on the Turnpike. They include the following studies:

- Relocation of the York Toll Plaza (MM 7.3)
- Improvements to the Gray Interchange (Exit 63)
- Improvements to the Lewiston Interchange (Exit 80)
- Improvements to the Gardiner I-295 Toll Plaza (MM 103.0)
- Exit 103/Route 126 intersection improvements
- Gorham East-West Corridor Feasibility Study
- Central York County Connections Study

## 2 INTRODUCTION

The following is a system-wide traffic operation and safety study of the Maine Turnpike (Turnpike) by HNTB Corporation, as requested by the Maine Turnpike Authority (Authority). This study includes an assessment of both current and future operating conditions of all interchanges, mainline sections, ramps, and toll plazas on the Turnpike between Kittery and Augusta. This study also includes an assessment of safety for all mainline sections, ramps, toll plazas, and intersections of local roads with Turnpike ramps.

This study is intended to present a broad look at safety and capacity needs on the Turnpike over the next 30 years. The purpose of this study is to provide information on needed capital improvements to help guide the Authority in the drafting of the 30 -Year Capital Plan. The Authority may also use this document for other purposes such as:

- Financial planning
- Construction planning
- Engineering
- Operations
- Maintenance
- Overall guidance

The parameters presented within this study include:

- A summary of current design hour traffic volumes (2011) for each mainline and ramp segment between Kittery and Augusta. Design hour volumes are the $30^{\text {th }}$ highest hour traffic volumes of a year.
- A forecast of future design hour traffic volumes at 10,20 , and 30 year horizons using applicable peak hour traffic growth rates and available forecasts.
- A highway and interchange capacity analyses for existing 10,20 , and 30 year design hour traffic volumes for mainline and ramps.
- A toll plaza operational analysis for existing, 10,20 , and 30 year design hour traffic volumes at each existing toll plaza location.
- An analysis of crash data from the most recent three year period for which data are available (2009-2011) along the Turnpike from Kittery to Augusta using data from the Maine Department of Transportation (MaineDOT).
- An analysis of Park and Ride lots adjacent to the Turnpike
- An evaluation of speeds from Exits 80-102
- Information from municipalities adjacent to the Turnpike regarding short or long term transportation improvements or problem areas

A series of recommendations are presented based on the data collected and results of the analyses performed. These include possible future improvements, an approximate time table of when the improvements will become necessary, and an estimate of the forecasted construction costs. Recommendations are also provided to address current safety needs at critical mainline, ramp, and intersection locations along the Turnpike.

It is important to note that, due to limitations in forecasting, the only solution to projected capacity constraints analyzed in this study is the physical addition of capacity. The Authority remains engaged in the ongoing process of exploring options which allow the existing roadway to operate more efficiently which can, in turn, delay the need for additional capacity. Several of these options have already been implemented and are continuously being considered for upgrades. Current programs include the following:

- Programs designed to encourage alternatives to single-occupant vehicles such as carpooling and rideshare through GOMaine, Zoom Bus Turnpike Express and attention to the maintenance and expansion of park and ride lots.
- Utilizing social media to inform Turnpike patrons (who have signed up for the service) of traffic issues on the Turnpike
- VMS (Variable Message Signs) in locations where unexpected changes in traffic flow are being experienced. Common examples are lane closures and detours.
- HAR (Highway Advisory Radio) System. This is a radio frequency which is accessible to patrons at most points along the Turnpike. The AM station is constantly broadcasting. Warnings are broadcast whenever there are traffic delays, construction activity, or weather related issues.
- CCTV (Closed Circuit Television) which is used to continually monitor six areas along the Turnpike. When traffic problems occur, a broadcast can be quickly recorded and played over the HAR system to alert patrons.

These programs are examples of the Authority's ongoing practice of taking a proactive stance when exploring alternative methods to improve capacity constraints.

The limitations in the scope of this study make it important to consider that it is only one of several planning tools used by the Authority. An example of an existing planning tool is the annual inspection report. The annual inspection report is used to determine capital and reserve maintenance needs based on the physical condition of the infrastructure assets.

In summary, this study identifies the approximate timeframe and cost for needed capacity and safety improvements on the Turnpike. While other programs and/or policies might be developed to help address safety and capacity, including alternative transportation methods, this report provides information on when these issues will arise and also provides basic estimates for the engineering and construction costs of adding these improvements to the highway.

Maine's Sensible Transportation Policy Act requires transportation agencies to identify and analyze alternatives to widening roadways in order to achieve capacity and safety needs. These alternatives have not been identified as part of this evaluation, however, will be done as a separate planning effort when necessary.

Outside of the course of this study, specific projects and issues have been identified that are being analyzed separately. They include the following studies:

- Relocation of the York Toll Plaza (MM 7.3)
- Improvements to the Gray Interchange (Exit 63)
- Improvements to the Lewiston Interchange (Exit 80)
- Improvements to the Gardiner I-295 Toll Plaza (MM 103.0)
- Exit 103/Route 126 intersection improvements
- Gorham East-West Corridor Feasibility Study
- Central York County Connections Study

Additionally, other possible improvements or projects may involve the need for advanced planning with MaineDOT and local municipalities including:

- Capacity needs on the Piscataqua River Bridge (also includes New Hampshire Department of Transportation)
- Study of traffic congestion in Saco
- Possible improvements to intersections adjacent to the Turnpike in Kittery, Wells, Biddeford, and Westbrook.

This study is written from a 2012 perspective using the most recent data available at the time. This study is an update to the previous Systemwide Traffic Operation and Safety Study that was completed in 2007. It is intended to be a working document which should be updated at regular intervals to account for changes in policy, traffic, and safety.

## 3 EXISTING CONDITIONS

In 1941, the Maine Turnpike Authority was created as an independent state agency and given the mandate to construct a turnpike "from some point at or near Kittery to a point at or near Fort Kent" as a means to help relieve congestion along coastal Route 1. The legislature intentionally delegated the responsibility for Turnpike construction, operation, and maintenance to the Authority and precluded any financial commitment by the state or federal government.

The original 45 miles of Turnpike from Kittery to Portland was opened to traffic in 1947 and Section II, from Portland to Augusta, was completed in 1955. The northern two-thirds of the 109 -mile Turnpike is a four-lane divided highway. The southern one-third is a six-lane divided highway. Turnpike facilities include 177 bridges (defined as any structure greater than 20 feet in length), 19 minor spans (defined as any structure 10-20 feet in length), 19 interchanges, 19 toll plazas, five service areas, nine maintenance facilities, and an administration building which includes retail space for Electronic Toll Collection (ETC), known as E-ZPass, and a State Police headquarters.

The Maine Turnpike is the major north-south highway in the state, extending from Kittery 200 feet north of Spruce Creek, to Augusta just south of Exit 109 (see Figure 3-1). The Turnpike today also includes a three-mile spur to Route 1 and Interstate 295 in Falmouth. The entire length of the Turnpike, from Kittery to Augusta is designated I-95. From Kittery to Portland, the Turnpike is the only interstate highway, making it one of the most critical elements of Maine's transportation network. The Authority is currently reviewing the possibility of purchasing an additional 1.9 miles of interstate from the MaineDOT in Kittery which will extend the Turnpike closer to the New Hampshire state border. For the purposes of this report that section of Interstate 95 is included.

Figure 3-1 - Map of Maine Turnpike

The demands placed on Turnpike facilities are enormous. Its roadways, bridges, interchanges, toll plazas, service areas, and maintenance areas are subjected to increasing stress due to age, traffic, and the demands of the harsh northern New England climate. To ensure the sound condition and effective operation of the Turnpike, the Authority has developed a 30 year plan which merges funding and the implementation of aggressive Operation and Maintenance, Reserve Maintenance, and Capital Improvement programs. The vigilance of the Authority through these programs has resulted in a well-maintained and efficiently operated Turnpike. The Authority will continue to improve Turnpike facilities regarding safety standards and projected demands.

### 3.1 Data Collection

The Authority collects and organizes extensive amounts of traffic data Turnpike-wide each year. The data being utilized in this study consists of those hourly traffic volumes continuously collected by the Authority's traffic count stations. These stations are located at every interchange and collect data from every on ramp, off ramp and mainline section of highway.

### 3.2 Traffic Characteristics

From the traffic data, the Authority can better understand the traffic patterns and historic growth of the Turnpike. The data provides information regarding variations throughout the mainline and among the interchanges. For example, some locations experience peak traffic during typical commuting periods, while other locations experience peak traffic that is more recreational or seasonal.

### 3.2.1 Average Annual Daily Traffic

Average Annual Daily Traffic (AADT) is the total volume of traffic on a highway segment for one year, divided by the number of days in the year. The AADT for 2011 was summarized for each highway segment and interchange ramp along the Turnpike. This AADT data indicates approximately how many vehicles are moving through a section of the mainline on an 'average' day of the year and can assist with future planning by providing a baseline number.

Figure 3-2 provides a tabular summary of AADT for the Turnpike in 2011. Each interchange is illustrated by a cluster of four boxes, each representing a ramp merging or diverging to and from the mainline. The boxes to the left of the center line represent the southbound (SB) ramps and the boxes to the right represent the northbound $(\mathrm{NB})$ ramps. The boxes between each cluster represent the AADT for the section of mainline it is adjacent to. A legend is provided in the bottom right hand corner of the figure.

Figure 3-2-2011 AADT Summary

Figure 3-2 illustrates the following traffic information for the year 2011:

- Total Recorded Vehicles/Day: 206,182
- Northbound Vehicles: 101,463
- Southbound Vehicles: 104,719
- Total Vehicles for 2011: 75,256,430
- The mainline link between the New Hampshire border and Exit 1 carried the heaviest average volume: 71,614 vehicles.
- Wells, Kennebunk, Biddeford and Saco interchanges have heavier traffic volumes to and from the North (Portland area) than to the South.
- All northern interchanges from Rand Rd to Sabattus have heavier traffic volumes to and from the South (Portland area) than to the North.

Table 3-1 compares AADT volumes for all mainline sections from 2001-2011. This data identifies overall growth for each mainline section of the Turnpike as well as the overall growth for the entire Turnpike.

Table 3-1 demonstrates that AADT on the various segments of the Turnpike grew in the early part of the decade until about 2004. Since that time, traffic levels have seen little growth. The section of the Turnpike south of Exit 32 had lower levels of daily traffic in 2011 than in 2001. The traffic levels on most of the mainline sections of the Turnpike north of Exit 32 are about 5-10\% higher in 2011 than in 2001.

Table 3-1 - AADT Mainline Volumes (Vehicles/Day)

### 3.2.2 Seasonal Variation

The Turnpike was originally opened with the intention of accommodating seasonal traffic and still exhibits a strong tourism component. It is important to understand the seasonal variations in traffic levels on the Maine Turnpike. Because of fluctuations in traffic levels an average summer weekday is sometimes much higher than an average winter weekday.

To demonstrate how traffic fluctuates seasonally on the Turnpike, three sections of the Turnpike were selected to display traffic variations. The section from the York to Wells Interchanges (miles 7-19) was chosen to represent the southern section of the Turnpike, which receives a lot of summer tourism traffic. The section from the Jetport to Rand Road Interchanges (miles 46-47) was chosen to represent the Portland region, which receives a lot of commuter traffic, but also summer tourism traffic. The section from the Gray to Auburn Interchanges (miles 63-75) represents the northern section, which receives less summer tourism traffic and a fair amount of commuter traffic. The seasonal traffic for each of these sections is shown in Figure 3-3.

Figure 3-3 - Seasonal Variation (Mainline Segments)

A few observations can be drawn from Figure 3-3:

- During the busy summer months of July and August the highest volumes occur in the southern end of the Turnpike.
- During the remaining months (September through June) the 2 lane central section carries higher average traffic volumes.
- All regions peak during the summer tourist season.
- The summer month increase is less dramatic in the central section and the northern section. The southern section increases by over $50 \%$ while the central and northern sections increase by $33 \%$ and $28 \%$, respectively.
- Approximately $31 \%$ of trips on the Turnpike occur during the months of June, July and August.

### 3.3 Existing Level of Service Analysis

The existing traffic conditions of all merge, diverge, and mainline travel areas (also known as basic freeway segments) were analyzed using current Highway Capacity Manual ${ }^{2}$ methods. The existing volume conditions evaluated in this document are the $30^{\text {th }}$ highest volumes occurring in the year 2011 as reported by the Authority's traffic count stations. $30^{\text {th }}$ highest volumes are calculated as the number of vehicles traveling a roadway segment during the $30^{\text {th }}$ ranked hour when the hours are organized from highest volume experienced to lowest. This design hour volume is a common industry standard in highway design.

All results are reported in terms of Level of Service (LOS), a qualitative measure describing operational conditions within a traffic stream. LOS is based on service measures such as speed and travel time, freedom to maneuver, traffic interruptions, comfort and convenience. Letters designate each level ranging from A to F where a LOS of A represents the best operating conditions and LOS F the worst. Most design or planning efforts typically use flow rates at LOS C or D to ensure adequate operating conditions. LOS of F represents unstable flows or a vehicle delay that is considered unacceptable. A more detailed description of LOS can be found in Appendix A. The general methodology and results of the analyses are outlined below.

### 3.3.1 LOS Analysis Assumptions

The parameters affecting Level of Service analysis consist of lane geometry, free-flow speed, driver familiarity with the roadway, the peak 15 minute traffic volume, and traffic composition (trucks, RV's and passenger car percentages). In this analysis the design hour volume was calculated for the $30^{\text {th }}$ highest hour from the year 2011 data and a peak hour factor of 0.95 was used to compute the peak 15 minute volume. Listed below are the assumptions which were made based on current traffic data to complete the Level of Service analysis.

- Based on previous speed studies taken on the Turnpike, a free-flow speed of 62 mph was used in all zones with a posted speed limit of 55 mph . In 65 mph speed limit zones a free-flow speed of 70 mph was used.
- Driver familiarity is captured in the model through a 'driver population adjustment factor'. A value of 1.0 is used when the drivers during the design hour are very familiar with the roadway i.e. commuter. A roadway with a majority of recreational drivers who are not familiar with the roadway would have a driver factor of 0.85 . In order to determine the appropriate driver factor, the 30 busiest hours at each location were analyzed. The following criteria was used:

[^1]0 If most of the 30 busiest hours were related to weekend traffic (Friday PM, Saturday, Sunday, or holidays), a factor of 0.85 was used.
o If the busiest hours were evenly split between weekdays and weekends, a factor of 0.90 was used.
o If the busiest hours were not closely correlated to weekend traffic at all, a factor of 1.00 was used.

- To determine a reasonable estimate for the ratio of trucks, recreational vehicles, and passenger cars operating on the mainline, average heavy vehicle percentages were obtained from toll plazas on the Turnpike that collect heavy vehicle data. From the traffic data, the following criteria was established:
o If the design hour is on a weekend afternoon, a ratio of $6 \%$ trucks - $3 \%$ RV's is used.
o If the design hour is on a weekday, a ratio of $7 \%$ trucks - $2 \%$ RV's is used.
The driver population adjustment factors, and the percentages of trucks and recreational vehicles that were used in the analysis, are located in Appendix B.

### 3.3.2 Interchange Merge Sections

A merge is defined as a movement in which two separate lanes of traffic combine to form a single lane without the aid of traffic signals or other right-of-way controls. In this situation the merge sections analyzed are on ramps at each interchange. The $30^{\text {th }}$ highest hour traffic volumes for both the ramp traffic and the mainline volume were analyzed for every case. A visual representation of a typical merge area is shown in Figure 3-4.

Figure 3-4 - Typical Merge Area

## NON-TYPICAL MERGE CASES

The merge point at Exit 103 in the northbound travel lane where I-295 merges with the Turnpike is considered a major merge area and was analyzed as a non-typical case. In a major merge, two primary roadways-each having multiple lanes-merge to form a single freeway segment. A visual of this form of major merge section is shown in Figure 3-5.

Figure 3-5- Major Merge Section

## MERGE ANALYSIS RESULTS

Table 3-2 displays both the $30^{\text {th }}$ highest hour 2011 traffic volumes for each on ramp and the corresponding volume on the mainline at that time. It also shows the $30^{\text {th }}$ highest hour traffic volume for the mainline segment at the merge point and the corresponding volume on the on ramp at that time. These volumes were determined by organizing all hourly volumes for a single year and selecting the $30^{\text {th }}$ highest volume. From these volumes the 'worst case scenario' - the situation which produced the lowest level of service at each merge section was selected. The calculations and analysis will be based on these worst case scenario values throughout the remainder of the document. The current LOS values for the worst case scenarios at each merge section are provided in Table 3-3.

## SUMMARY OF FINDINGS

As can be seen from Table 3-3, all of the merge areas are currently operating at acceptable levels of service.

Table 3-2-2011 Volumes at Merge Sections

### 3.3.3 Interchange Diverge Sections

A diverge is defined as a movement in which a single traffic stream separates into two traffic streams without the aid of traffic control devices. The diverge sections analyzed are off ramps at each interchange. The $30^{\text {th }}$ highest hour 2011 traffic volumes were found for both the ramp traffic and the mainline traffic. Both of these scenarios were analyzed for every diverge section. A visual representation of a typical diverge area is represented in Figure 3-6.

Figure 3-6 - Typical Diverge Section

## NON-TYPICAL DIVERGE CASES

Three interchanges along the Turnpike have diverge areas that are considered non-typical, Exits 36, 44, and 103. These diverge areas were analyzed by methods described in the following sections.

Exit 36
The exit 36 northbound off ramp is preceded by an on ramp which services the Saco Conference Center. Since these two ramps fall within a 1,500 foot distance of each other the area is classified as a weave section and analyzed using a different method. Figure 3-7 depicts a Type A weave area (as defined by the Highway Capacity Manual). Figure 3-8 shows the paths of travel analyzed as inputs.

Figure 3-7- Type A Traffic Weave Segment

Figure 3-8- Travel Paths in Type A Traffic Weave Segment

Specific data concerning the volumes of traffic from stations A-D, A-C, B-D, and B-C as shown in the above diagram were not known. The volume from station B-D was assumed to be small amount of traffic, about $5 \%$ of the 687 vehicles counted at point D. Volume B-C was assumed to be a traffic volume similar to volume B-D, which is a relatively small fraction compared to the known mainline volume A-C of $3,900 \mathrm{vph}$.

Exits 44 \& 103
Exit 44 in the northbound direction and Exit 103 in the southbound direction are two-lane off ramps. The geometry of this configuration is shown in Figure 3-9.

Figure 3-9- Major Diverge Section

To analyze this case, equation 13-26 from the Highway Capacity Manual was used. The equation reads:

$$
\mathrm{D}_{\mathrm{MD}}=0.0175^{*} \mathrm{~V}_{\mathrm{f}} / \mathrm{N}
$$

where
$\mathrm{N}=$ number of lanes approaching major diverge
$\mathrm{V}_{\mathrm{f}}=$ demand flow rate immediately upstream, of the major diverge influence area ( $\mathrm{pc} / \mathrm{h}$ )
$\mathrm{D}_{\mathrm{MD}}=$ density in the major diverge influence area (which includes all approaching freeway lanes) in passenger cars/hour

The density value calculated was then converted into a LOS rating using Exhibit 25-4 in the Highway Capacity Manual. The detailed calculations can be found in Appendix C.

Table 3-4 displays the current $30^{\text {th }}$ hour 2011 traffic volumes for each off ramp and the corresponding volume on the mainline at that time. It also shows the $30^{\text {th }}$ highest hour traffic volume for the mainline segment at the point of divergence and the corresponding traffic volume on the off ramp at that time. From these volumes the 'worst case scenario' (the situation which produced the lowest level of service at each diverge section) was selected. The calculations and analysis will be based on these worst case scenario values throughout the remainder of the document. The current LOS values for the worst case scenarios at each diverge section are provided in Table 3-5.

## SUMMARY OF FINDINGS

As can be seen from Table 3-5, under current traffic conditions, all of the diverge areas are operating at acceptable levels of service.

### 3.3.4 Mainline Travel Sections

A basic freeway segment is defined as a length of freeway facility whose operations are unaffected by weaving, diverging or merging. These occur between all interchanges along the freeway. The parameters affecting this analysis are lane geometry, free-flow speed, an adjustment factor for driver's familiarity with the roadway, and the peak 15 minute volume. In this analysis, the design hour traffic volume was calculated for the $30^{\text {th }}$ highest hour from the year 2011 data and a peak hour factor of 0.95 was used to compute the peak 15 minute volume. Table 3-6 shows the design hour volumes and the level of service for all of the mainline sections of the Turnpike.

## SUMMARY OF FINDINGS

All sections of mainline are operating at or above the desired levels of service with the exception of miles $0-2$ in the northbound direction and $0-1$ in the southbound direction. These are busy 3 lane sections that are also impacted by the adjacent bridge over the Piscataqua River. Traffic between Exits $0-2$ is constrained by the Piscataqua River Bridge. Because of capacity issues, coordination with the

New Hampshire Department of Transportation will be needed in the near future concerning the Piscataqua River Bridge.

Table 3-6-2011 Volumes and LOS for Mainline Sections

| Segment | Northbound <br> Mainline |  | Southbound <br> Mainline |  |

### 3.3.5 Summary - Existing Level of Service Analysis

Overall the Maine Turnpike is currently functioning at acceptable Levels of Service.

- All merge segments meet or exceed the LOS grade of D which provides acceptable operating conditions.
- All diverge segments meet or exceed the LOS grade of D which provides acceptable operating conditions.
- Three mainline segments (all of which were located south of Exit 2 in Kittery) received a grade of E which is characterized by significant delays and average travel speeds of $33 \%$ or less of the free flow speed. All other segments fell in or above the desired level of service.

## 4 FUTURE CONDITIONS

Future traffic volumes on the Maine Turnpike were calculated using a fixed annual growth rate. Forecasted 10, 20, and 30 year volumes were compounded annually using the 2011 data as base volumes. The following sections detail the calculations and assumptions used to establish the growth rate and show the forecasted volumes and corresponding levels of service.

Other projects and developments may have an impact on future traffic, such as the Gorham EastWest Corridor Study, but those impacts are not yet established. These studies and potential developments are discussed further in Sections 7 and 9.

### 4.1 Growth Rate Calculations

In order to calculate the forecasted traffic volumes in 10, 20, and 30 years, a peak hour growth rate was determined. A summary of peak hour annual growth rates for all mainline sections on the Turnpike is shown in Table 4-1.

Different regions of the Turnpike have varying growth rates, with most mainline sections growing an average of $0-2 \%$ per year. The overall average peak hour growth rate for the Turnpike between 2000 and 2011 was $1.1 \%$. It was decided that the overall annual growth rate of $1.1 \%$ for the Turnpike should be used to estimate future peak hour traffic growth instead of varying growth rates for the different regions of the Turnpike. Recent toll rate adjustments have had varying impacts on traffic growth in the different regions of the Turnpike, and it can be expected that the upcoming November 2012 toll adjustment will not have similar impacts to the different regions. The assumed growth rate value of $1.1 \%$ is comparable to the traffic growth rate used in recent traffic and revenue projections.

Table 4-1 - Annual Peak Hour Growth Calculations

| Region | Link | Direction | 30th highest hour |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

### 4.2 Interchange Merge Sections

A forecasted timeline was established for each merge section regarding when it is expected to receive a Level of Service rating of E and F. LOS E indicates that the section of roadway is at capacity. At LOS E small interruptions in traffic flow can cause traffic congestion. LOS E, therefore, is a good indicator that improvements will need to be made in the near future and the permitting process should begin. The year that a merge section is forecasted to reach LOS F is a desirable time to begin construction. Table 4-2 illustrates this timeline. LOS values in Table 4-2 are based on predicted volumes from the 'worst case scenario' presented in Section 3.3.2. The volumes used as well as a table presenting the 10 , 20, and 30 year forecasted levels-of-service can be found in Appendix D.

There are a few important trends to note about Table 4-2:

- Most merge areas will not reach capacity within the 30 year scope.
- All merge areas at Exits 1 and 2 will need attention within the next 30 years.
- The York southbound, Saco southbound, South Portland northbound, Jetport northbound, Rand Road northbound and southbound merge areas are expected to reach capacity within 30 years.

It is possible for either a mainline segment or a ramp segment to reach capacity before the ramp's merge area does. In these cases widening of the segment that is operating at capacity will prevent the predicted merge area failure. A timeline displaying the estimated year for each on-ramp segment to reach capacity is shown in Table 4-3.

The ramp segments were assessed in a different manner than the merge areas. Level-of-service can be calculated for merge areas. Conversely, there is no method for calculating LOS for ramp segments. The ramps were analyzed as having a fixed capacity ( 1,650 vehicles per lane per hour ${ }^{3}$ ) and they are either above or below capacity.

Table $4-3$ suggests the following on ramp segments are expected to reach capacity within 30 years:

- Exit 2 - Kittery - Southbound
- Exit 32 - Biddeford - Northbound
- Exit 36 - Saco - Northbound
- Exit 44 - I-295 - Southbound

[^2]Table 4-2 - Year When Merge Areas Reach LOS E and F

*Exit 44 southbound on-ramp is a two-lane ramp that becomes one lane before the merge with the Turnpike. It therefore effectively acts as a one lane ramp.

### 4.3 Interchange Diverge Sections

A forecasted timeline was established for each diverge section regarding when it is expected to receive a Level of Service rating of E and F. LOS E indicates that the section of roadway is at capacity. At LOS E small interruptions in traffic flow can cause traffic congestion. LOS E, therefore, is a good indicator that improvements will need to be made in the near future and the permitting process should begin. The year that a diverge section is forecasted to reach LOS F is a desirable time to begin construction. Table 4-4 illustrates this timeline. LOS values are based on predicted volumes from the 'worst case scenario' presented in Section 3.3.2. The volumes used as well as a table presenting the 10, 20, and 30 year forecasted Levels of Service can be found in Appendix D.

Table 4-4 illustrates the diverge areas that will receive a Level of Service rating of E or F within the next 30 years. A few important trends to note:

- Four diverge areas within the central portion of the Turnpike between Scarborough and Falmouth are expected to reach capacity within 30 years.
- All of the diverge areas in the town of Kittery are expected to reach capacity within the 30 year scope.
- Within the next 30 years all diverge areas at the Saco interchange are forecasted to experience failing design hour LOS ratings.
- The York northbound off-ramp diverge area is expected to receive a failing LOS grade within 30 years.
- Exits north of Falmouth are not expected to receive a failing LOS grade within 30 years.

It is possible for either a mainline segment or a ramp segment to reach capacity before the ramp's diverge area does. In these cases widening of the segment that is operating at capacity will prevent the predicted diverge area failure. A timeline displaying the estimated year for each off-ramp segment to reach capacity is shown in Table 4-5.

The ramp segments were assessed in a different manner than the diverge areas. Level-of-service can be calculated for diverge areas. Conversely, there is no method for calculating LOS for ramp segments. The ramps were analyzed as having a fixed capacity (in this case 1,650 vehicles per lane per hour ${ }^{4}$ ) and they are either above or below capacity.

Only two diverge ramps are expected to reach capacity in the next 30 years: Biddeford southbound and Saco southbound.

[^3]Table 4-4 - Year When Diverge Areas Reach LOS E and F

### 4.4 Mainline Sections

LOS values are based on predicted mainline volumes from Section 3.3.4. A forecasted timeline was established for each mainline section regarding when it is expected to receive a Level of Service rating of E and F . LOS E is a good indicator that improvements will need to be made in the near future and
the permitting process should begin. It is desirable to begin construction before a mainline section reaches LOS F to avoid unreasonable delays and situations which could compromise safety.

Table 4-6 summarizes the calendar years during which each segment is anticipated to be servicing a volume high enough to produce a LOS rating of E and F . The volumes used as well as a table presenting the 10, 20, and 30 year forecasted Levels of Service can be found in Appendix D.

Table 4-6 illustrates which mainline sections of the Turnpike will receive a LOS grade of E or F due to capacity within the next 30 years. Below is a summary of when capacity improvements will be needed:

- Within 10 years:
o Miles 0-1 between the New Hampshire state line and Kittery in the NB direction.
- Within 20 years:
o Miles 1-2 between the two Kittery exits in the NB direction
o Miles 0-2 between the New Hampshire state line and Kittery in the SB direction.
o Miles 46-48 from the Jetport interchange to the Riverside interchange in the NB direction.
- Within 30 years:
o Miles 2-7 from Kittery to York in both directions.
o Miles 44-46 from the I-295 interchange to the Jetport interchange in the NB direction.
o Miles 44-47 from the I-295 interchange to the Rand Road interchange in the SB direction.

In general, mainline sections for the northbound travel direction reach capacity several years before the southbound travel direction. For the purposes of permitting, the northbound and southbound sections should be grouped together. However, for construction planning, one travel direction on the Turnpike could be widened at a different time from the other.

Table 4-6 - Year When Mainline Segments Reach LOS E and F

| Segment | Location | NB Mainline |  | SB Mainline |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | LOS E | LOS F | LOS E | LOS F |
| 0-1 | NH Border to Kittery Exit 1 | 2008 | 2020 | 2010 | 2022 |
| 1-2 | Kittery Exit 1 to 2 | 2015 | 2026 | 2019 | 2030 |
| 2-7 | Kittery to York | 2024 | 2036 | 2023 | 2035 |
| 7-19 | York to Wells | 2040 | Beyond 2041 | 2037 | Beyond 2041 |
| 19-25 | Wells to Kennebunk | Beyond 2041 | Beyond 2041 | 2040 | Beyond 2041 |
| 25-32 | Kennebunk to Biddeford | Beyond 2041 | Beyond 2041 | 2041 | Beyond 2041 |
| 32-36 | Biddeford to Saco | 2032 | Beyond 2041 | 2031 | Beyond 2041 |
| 36-42 | Saco to Scarborough | 2036 | Beyond 2041 | 2032 | Beyond 2041 |
| 42-44 | Scarborough to I-295 | 2039 | Beyond 2041 | 2038 | Beyond 2041 |
| 44-45 | I-295 to Maine Mall Rd. | 2021 | 2034 | 2024 | 2037 |
| 45-46 | Maine Mall Rd. to Jetport | 2025 | 2038 | 2028 | 2040 |
| 46-47 | Jetport to Rand Rd. | 2012 | 2025 | 2024 | 2037 |
| 47-48 | Rand Rd. to Riverside | 2017 | 2030 | 2029 | Beyond 2041 |
| 48-52 | Riverside to Falmouth | 2029 | Beyond 2041 | 2033 | Beyond 2041 |
| 52-53 | Falmouth to West Falmouth | 2035 | Beyond 2041 | Beyond 2041 | Beyond 2041 |
| 53-63 | West Falmouth to Gray | Beyond 2041 | Beyond 2041 | Beyond 2041 | Beyond 2041 |
| 63-75 | Gray to Auburn | Beyond 2041 | Beyond 2041 | Beyond 2041 | Beyond 2041 |
| 75-80 | Auburn to Lewiston | Beyond 2041 | Beyond 2041 | Beyond 2041 | Beyond 2041 |
| 80-86 | Lewiston to Sabattus | Beyond 2041 | Beyond 2041 | Beyond 2041 | Beyond 2041 |
| 86-102 | Sabattus to West Gardiner | Beyond 2041 | Beyond 2041 | Beyond 2041 | Beyond 2041 |
| 102-103 | West Gardiner to Gardiner | Beyond 2041 | Beyond 2041 | Beyond 2041 | Beyond 2041 |
| 103-109 | Gardiner to End of Turnpike | Beyond 2041 | Beyond 2041 | Beyond 2041 | Beyond 2041 |

${ }^{*}$ The mainline segment from Spruce Creek to the York Interchange will eventually be metered by the number of lanes on the Piscataqua Bridge at the NH border. This bottleneck effect may cause growth in this region to slow and keep LOS volumes from reaching a failing grade when anticipated. It is recommended that this area be monitored and assessed during the coming years.

### 4.5 Summary of Future Conditions

Table 4-7 and Table 4-8 each present a year-by-year summary of when each interchange, mainline, and ramp on the Turnpike is forecasted to reach LOS F. The evaluated areas include on- and offramps, diverge and merge areas, and mainline segments.

Table 4-7 - Areas between Kittery \& Exit 44 Reaching LOS F, 2011-2041

| Physical Location | 2015 | 2016 | 2017 | 2018 | 2019 | 2020 | 2021 | 2022 | 2023 | 2024 | 2025 | 2026 | 2027 | 2028 | 2029 | 2030 | 2031 | 2032 | 2033 | 2034 | 2035 | 2036 | 2037 | 2038 | 2039 | 2040 | 2041 |

| Sabattus to West Gardiner (86-102) |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| West Gardiner Exit 102 |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| West Gardiner to Gardiner (102-103) |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| Gardiner Exit 103 |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| Gardiner to End of Turnpike (103-109) |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |

1 The timeline for capacity improvements in the Portland area could be affected by the results of the Gorham East-West Corridor Feasibility Study

As can be seen from Table 4-7 and Table 4-8, a few large project groups that may be reasonably planned together include the following:

- The southern portion of the mainline from the New Hampshire state line to the York interchange may need to be widened beginning in 2017.
- The Saco interchange may need to be updated beginning in 2019.
- The SB I-295 Exit 44 on ramp may need to be widened to accommodate two merging lanes in the year 2023.
- The Portland area widening, from Exit 44 (I-295) to Exit 48 (Westbrook), may need to begin in the year 2025 to avoid capacity constraints.
- The Biddeford interchange may need to be updated beginning in 2031.

## 5 PARK AND RIDE ANALYSIS

The Authority builds and maintains eleven Park and Ride lots for patrons. The MaineDOT maintains an additional six Park and Ride lots located adjacent to the Turnpike. As a result, a Park and Ride lot is located near most Turnpike interchanges.

Every year a survey of Park and Ride lot usage is conducted in conjunction with the Authority's annual report ${ }^{5}$. The count is always completed in the spring, generally during the months of April or May. Vehicle counts at each lot are taken during the mid-day hours ( $9 \mathrm{am}-3 \mathrm{pm}$ ) on weekdays in order to capture commuting vehicles. This count is performed as a way to monitor lot usage; although, it only provides a snapshot of the overall usage of the lots. The location, capacity, and historical usage of each lot are shown in Table 5-1. Table 5-2 shows the utilization of the park and ride lots since 2001.

[^4]Table 5-1- Park and Ride Locations, Capacities \& Usage

| Town | Location | Owner | Capacity | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 | 2009 | 2010 | 2011 | 2012 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| Saco | I-195 Exit 1, overflow lot off Rte. 112 | MaineDOT | 52 |  |  |  |  |  |  |  |  |  |  |  | 2 |
| Scarborough | Maine Turnpike Exit 42, adj. to toll plaza | MTA | 65 | 25 | 16 | 13 | 24 | 30 | 18 | 27 | 17 | 23 | 20 | 30 | 26 |
| South Portland | Maine Turnpike Exit 45, on Rt. 703 | MaineDOT | 111 | 24 | 23 | 42 | 29 | 32 | 22 | 24 | 28 | 20 | 26 | 32 | 37 |
| Portland | Maine Turnpike Exit 46, adj. to toll plaza | MTA | 68 | 8 | 14 | 8 | 21 | 17 | 17 | 21 | 20 | 19 | 25 | 8 | 21 |
| Westbrook | Larrabee Road, near Maine Turnpike Exit 47 | MaineDOT | 91 |  |  | 46 | 43 | 43 | 51 | 43 | 53 | 47 | 36 | 26 | 48 |
| W. Falmouth | Maine Turnpike Exit 53, adj. to toll plaza | MTA | 19 | 4 | 14 | 15 | 14 | 19 | 13 | 15 | 20 | 15 | 12 | 6 | 8 |
| Gray | Maine Turnpike Exit 63, on US-202 | MTA | 75 | 45 | 29 | 41 | 57 | 59 | 46 | 34 | 77 | 50 | 68 | 57 | 64 |
| Auburn | Maine Turnpike Exit 75, on US-202 | MTA | 137 | 57 | 81 | 75 | 68 | 92 | 76 | 71 | 106 | 72 | 71 | 94 | 82 |
| Lewiston-1 | Maine Turnpike Exit 80 NB on Plourde Pkwy | MTA | 62 | 26 | 44 | 41 | 53 | 38 | 56 | 28 | 47 | 27 | 25 | 35 | 60 |
| Lewiston-2 | Maine Turnpike Exit 80 SB on Plourde Pkwy | MTA | 27 | 16 | 17 | 23 | 22 |  | 21 | 21 | 28 | 22 | 20 | 26 | 25 |
| Sabattus | Maine Turnpike Exit 86, intersection of Rt. 9 \& 126 | MaineDOT | 30 |  |  |  |  |  |  |  |  |  |  |  | 26 |
| W. Gardiner | Maine Turnpike Exit 102, near Rt. 126 | MTA | 54 |  | 25 | 28 | 34 | 43 | 27 | 28 | 50 | 29 | 25 | 24 | 30 |

A few things to note about Table 5-1 are:

- In 2012, 733 vehicles were counted in lots located throughout the Maine Turnpike corridor, which is about $58 \%$ of the available capacity of the Park \& Ride lots.
- The Saco lot was recently expanded to include a second lot near Route 112. This lot is not heavily used yet, possibly due to patrons not being aware of its location.
- Though the Sabattus lot has been open for several years, this is the first year this lot was counted as part of the Maine Turnpike's annual inspection.

Table 5-2 - Surveyed Percent Usage of Park \& Ride Lots

| Town | Location | Owner | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 | 2009 | 2010 | 2011 | 2012 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| York | Chases Pond Road, US-1 Connector | MaineDOT | 77\% | 65\% | 62\% | 35\% | 58\% | 31\% | 42\% | 100\% | 85\% | 62\% | 58\% | 100\% |

| Saco | I-195 Exit 1, overflow lot off Rte. 112 | MaineDOT |  |  |  |  |  |  |  |  |  |  |  | 4\% |
| Scarborough | Maine Turnpike Exit 42, adj. to toll plaza | MTA | 109\% | 70\% | 57\% | 104\% | 130\% | 78\% | 117\% | 74\% | 35\% | 31\% | 46\% | 40\% |
| South Portland | Maine Turnpike Exit 45, on Rt. 703 | MaineDOT | 22\% | 21\% | 38\% | 26\% | 29\% | 20\% | 22\% | 25\% | 18\% | 23\% | 29\% | 33\% |
| Portland | Maine Turnpike Exit 46, adj. to toll plaza | MTA | 12\% | 21\% | 12\% | 31\% | 25\% | 25\% | 31\% | 29\% | 28\% | 37\% | 12\% | 31\% |
| Westbrook | Larrabee Road, near Maine Turnpike Exit 47 | MaineDOT |  |  | 51\% | 47\% | 47\% | 56\% | 47\% | 58\% | 52\% | 40\% | 29\% | 53\% |
| W. Falmouth | Maine Turnpike Exit 53, adj. to toll plaza | MTA | 21\% | 74\% | 79\% | 74\% | 100\% | 68\% | 79\% | 105\% | 79\% | 63\% | 32\% | 42\% |
| Gray | Maine Turnpike Exit 63, on US-202 | MTA | 60\% | 39\% | 55\% | 76\% | 79\% | 61\% | 45\% | 103\% | 67\% | 91\% | 76\% | 85\% |
| Auburn | Maine Turnpike Exit 75, on US-202 | MTA | 42\% | 59\% | 55\% | 50\% | 67\% | 55\% | 52\% | 77\% | 53\% | 52\% | 69\% | 60\% |
| Lewiston-1 | Maine Turnpike Exit 80 NB on Plourde Pkwy | MTA | 42\% | 71\% | 66\% | 85\% | 61\% | 90\% | 45\% | 76\% | 44\% | 40\% | 56\% | 97\% |
| Lewiston-2 | Maine Turnpike Exit 80 SB on Plourde Pkwy | MTA | 59\% | 63\% | 85\% | 81\% |  | 78\% | 78\% | 104\% | 81\% | 74\% | 96\% | 93\% |
| Sabattus | Maine Turnpike Exit 86, intersection of Rt. 9 \& 126 | MaineDOT |  |  |  |  |  |  |  |  |  |  |  | 87\% |
| W. Gardiner | Maine Turnpike Exit 102, near Rt. 126 | MTA |  | 46\% | 52\% | 63\% | 80\% | 50\% | 52\% | 93\% | 54\% | 46\% | 44\% | 56\% |

Note: Highlighted cells indicate the surveyed usage was found to be greater than $75 \%$.

Some historical trends and information for the Turnpike's lots were observed when looking over the last 12 years:

- The lots that have the most available capacity and not currently a concern are Wells, Kennebunk, Scarborough (which was recently expanded), and Portland/Jetport.
- The Biddeford lot does not seem to be in need of immediate expansion even though the percent usage was above $75 \%$ three times between 2001 and 2007. In the past five years the counts have declined. This lot should be watched closely, if usage rebounds capacity may become an issue.
- The Saco lot on Industrial Park road is well utilized (over $75 \%$ of capacity in 9 of the last 12 years). This lot is DOT owned. The DOT has recently constructed a smaller lot nearby on Route 112 in response to the heavy demand.
- The West Falmouth lot does not seem to be in need of immediate expansion even though the percent usage was above $75 \%$ five times between 2003 and 2009. In the past three years the counts have declined considerably. This lot has been studied in the past. It was determined that the lot cannot be expanded at its current location and that no suitable nearby sites were found for another park and ride lot.
- The Gray lot has been above $75 \%$ of capacity for four out of the last five years. The Gray Interchange is being studied. Possible relocation of the park and ride lot is part of that study.
- The Auburn lot has exceeded $75 \%$ of its capacity in only one of the years studied.
- The two lots near the Lewiston exit are consistently above $75 \%$ capacity. A new interchange in Lewiston is currently in the 30 -year plan. Due to the re-design of the Exit 80 interchange, a larger, single, relocated, park and ride lot is being built and is scheduled to be open late fall 2012
- The West Gardiner lot was counted at $80 \%$ and $93 \%$ capacity in 2005 and 2008, respectively. Since 2009 usage has been closer to $50 \%$ and no longer appears to be a problem.

Some historical trends and information for the MaineDOT owned lots can also be recognized when looking over the last 12 years:

- The lots that are least used and not currently a concern are the newly created Saco (Route 112), South Portland, and Westbrook.
- Usage at the York lot has been above $75 \%$ of capacity during 3 of the last 5 years.
- The Saco lot on Industrial Park road is well utilized (over $75 \%$ of capacity in 9 of the last 12 years). The DOT has recently constructed a smaller lot nearby on Route 112 in response to the heavy demand.
- The Sabattus lot was surveyed at $87 \%$ of capacity in 2012 but there is no historical data to verify this as a trend.

## 6 TOLL PLAZA ANALYSIS

The Maine Turnpike Authority operates 19 toll plazas. Six of these plazas are located on the highway itself, tolling traffic in both directions. These larger plazas, sometimes referred to as "mainline toll plazas", range in size from 6 lanes to 17 lanes. The remaining 13 plazas are located on various interchange ramps and are responsible for tolling patrons that enter the Turnpike. These "side toll plazas" do not collect tolls on the lanes that exit the Turnpike. These smaller plazas are between 2 and 4 tolled lanes wide. Table 6-1 summarizes the MTA's toll plaza locations and sizes.

Table 6-1 -Toll Plaza Location and Size Summary

| Mainline Toll Plazas |  | Side Toll Plazas | \# of Lanes |
| :--- | :--- | :--- | :--- |
| Location | 17 | Lanes | Location |
| York | 8 | Kells (Exit 19) | 2 |
| I-295 (Exit 44) | 6 | Kennebunk (Exit 25-NB Ramp) | 2 |
| Falmouth Spur | 10 | Kennebunk (Exit 25-SB Ramp) | 2 |
| New Gloucester | 8 | Siddeford (Exit 32) | 3 |
| W. Gardiner (I-95) | 7 | Saco (Exit 36) | 3 |
| Gardiner (I-295) | Scarborough (Exit 42) | 3 |  |
|  |  | South Portland (Exit 45) | 4 |
| Jetport (Exit 46-NB Ramp) | 2 |  |  |
|  |  | Jetport (Exit 46-SB Ramp) | 2 |
|  | Rand Rd. (Exit 47) | 3 |  |
|  |  | Riverside (Exit 48) | 4 |
|  | W. Falmouth (Exit 53) | 2 |  |
|  | Gray (Exit 63) | 2 |  |

The purpose of HNTB's analysis was to identify which (if any) plazas will need to be expanded or otherwise improved over the next 30 years. The scope of the analysis covered all plazas except York, W. Gardiner (I-95), and Gardiner (I-295). These plazas are being evaluated under two separate ongoing studies. ${ }^{6}$

The toll plaza analysis involved three basic steps for each toll plaza:

- First, the design-hour volume for 2011 was identified. In keeping with standard traffic engineering practice, the design hour volume is considered to be the $30^{\text {th }}$ highest hour experienced by the plaza over a year. The design hour volume was broken down into two categories:
o Cash patrons (i.e. patrons that hand a cash fare directly to a toll attendant)
o ETC patrons (i.e. patrons that pay their fare via Electronic Toll Collection)

[^5]- Second, the current-year design hour volumes were projected out over a 30 -year period, from 2011 through 2041. This required estimating both the overall growth in traffic levels and the growth of ETC usage over time.
- Third, the volume-to-capacity ratio was calculated for each year between 2011 and 2041. The evaluation was based on the existing configuration of the toll plaza (that is, the existing mix of cash and dedicated E-ZPass lanes). If at any time a plaza's demand exceeded its capacity-that is, if the volume-to-capacity ratio was greater than one-then the plaza was identified as being in need of improvement.

### 6.1 Design-Hour Volume Summary

Table 6-2 identifies the design hour volumes (DHV's) for each plaza in 2011. The table also identifies the day of the week on which the design hour volume typically occurs. At the mainline toll plazas, both the northbound and southbound DHV's are provided.

Table 6-2 - Toll Plaza Design-Hour Volume Summary

| Location | Peak Period | Design Hour Volume |  |  | \%ETC |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Cash | ETC | Total |  |
| Mainline Toll Plazas (excluding York, W. Gardiner (I-95), and Gardiner (I-295) |  |  |  |  |  |
| I-295 (SB entering Tpk) | Summer Weekend (PM) | 511 | 921 | 1,432 | 64.3\% |
| I-295 (NB exiting Tpk) | Spring/Fall Weekday (AM) | 440 | 671 | 1,111 | 60.4\% |
| Falmouth Spur (entering Tpk) | Summer Weekend (Midday) | 385 | 450 | 835 | 53.9\% |
| Falmouth Spur (exiting Tpk) | Summer Weekend (Midday) | 314 | 455 | 768 | 59.2\% |
| New Gloucester (NB) | Summer Friday (PM) | 487 | 411 | 898 | 45.8\% |
| New Gloucester (SB) | Summer Sunday (Midday) | 576 | 474 | 1,050 | 45.1\% |
| Side Toll Plazas |  |  |  |  |  |
| Wells | Summer Weekend (PM) | 199 | 240 | 439 | 54.7\% |
| Kennebunk (NB Ramps) | Spring/Fall Weekday (AM) | 87 | 411 | 498 | 82.4\% |
| Kennebunk (SB Ramps) | Summer Sunday (Midday) | 97 | 156 | 253 | 61.6\% |
| Biddeford | Spring/Fall Weekday (AM) | 362 | 1,158 | 1,520 | 76.2\% |
| Saco | Spring/Fall Weekday (AM) | 440 | 1,531 | 1,971 | 77.7\% |
| Scarborough | Summer Weekday (PM) | 255 | 413 | 668 | 61.8\% |
| South Portland | Summer Weekday (PM) | 467 | 1,004 | 1,471 | 68.3\% |
| Jetport (NB Ramps) | Weekday (PM) | 213 | 716 | 930 | 77.1\% |
| Jetport (SB Ramps) | Weekday (PM) | 91 | 430 | 521 | 82.5\% |
| Rand Road | Weekday (PM) | 241 | 448 | 689 | 65.0\% |
| Riverside Street | Summer Friday (PM) | 351 | 449 | 800 | 56.1\% |
| West Falmouth | Spring/Fall Weekday (AM) | 155 | 749 | 904 | 82.9\% |
| Gray | Spring/Fall Weekday (AM) | 256 | 783 | 1,039 | 75.4\% |

The following observations may be drawn from Table 6-2:

- The side toll plazas tend to experience their peak volumes during weekdays. This is because these plazas serve a significant number of commuters, and commuting volumes are higher on
weekdays than weekends. By contrast, mainline toll plazas serve a greater proportion of recreational travelers from out-of-state, and these customers tend to travel in greater numbers on weekends.
- The side toll plazas tend to have a higher percentage of ETC usage during peak periods, as compared to the mainline toll plazas. In fact, seven of the thirteen side toll plazas have design-hour ETC usage in the $75-85 \%$ range. The design-hour ETC usage exceeds $60 \%$ at all but one side toll plaza (Riverside St.).
- The busiest side toll plaza is Saco, which has 3 lanes serving nearly 2,000 vehicles during the design hour.
- Three side toll plazas (Jetport NB, W. Falmouth, and Gray) serve over 900 design-hour vehicles despite only having two lanes. This is only possible because of the high level of ETC usage.

### 6.2 Toll Plaza Traffic Projections

After identifying the current-year design hour volumes, it was necessary to develop 30 -year projections. These projections would serve as the basis for the plaza capacity analysis.

The projections were based on the following assumptions:

- Design-hour traffic would grow at an annual rate of $1.1 \%$ for all locations, consistent with the growth rate documented in Section 4.1.
- The percentage of ETC traffic would increase over time. However, this rate of increase would decline over time, and it would reach a practical maximum value of $80 \%$.

Table 6-3 provides a year-by-year projection of design-hour volumes and ETC usage for each mainline toll plaza through 2041. Table 6-4 provides the same information for the side toll plazas. The plazas at York, West Gardiner and Gardiner are not included in this analysis; separate detailed studies are being completed to address these locations.

All volumes are based on 2011 data, since 2011 was the last full calendar year for which toll plaza data was available. The only exceptions to this are the plazas at Exit 47 (Rand Rd.) and Exit 48 (Riverside St.). The volumes at these plazas are based on 2010 data. This is because the 2011 data at these plazas was distorted by construction at Exit 48. Since the northbound on-ramp at Exit 48 was closed for most of 2011, a significant volume of traffic shifted from Exit 48 over to Exit 47 . Once the northbound on-ramp re-opened in November 2011, traffic patterns at both plazas returned to normal.

Table 6-3-Mainline Toll Plaza Design Hour Traffic Projections

| Year | I-295 (NB) |  | I-295 (SB) |  | Falmouth Spur (Enter) |  | Falmouth Spur (Exit) |  | New Gloucester (NB) |  | New Gloucester (SB) |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Vol. | ETC\% | Vol. | ETC\% | Vol. | ETC\% | Vol. | ETC\% | Vol. | ETC\% | Vol. | ETC\% |
| 2011 | 1,111 | 60.4\% | 1,432 | 64.3\% | 835 | 53.9\% | 768 | 59.2\% | 1,175 | 61.8\% | 1,047 | 45.1\% |
| 2012 | 1,123 | 61.6\% | 1,448 | 65.1\% | 844 | 56.0\% | 777 | 61.3\% | 1,188 | 63.1\% | 1,059 | 47.2\% |
| 2013 | 1,135 | 62.9\% | 1,464 | 66.0\% | 853 | 58.2\% | 786 | 62.6\% | 1,201 | 64.3\% | 1,071 | 49.4\% |
| 2014 | 1,147 | 64.1\% | 1,480 | 66.8\% | 862 | 60.3\% | 795 | 63.8\% | 1,214 | 65.6\% | 1,083 | 51.5\% |
| 2015 | 1,160 | 65.4\% | 1,496 | 67.6\% | 871 | 61.6\% | 804 | 65.1\% | 1,227 | 66.8\% | 1,095 | 53.7\% |
| 2016 | 1,173 | 66.6\% | 1,512 | 68.5\% | 881 | 62.8\% | 813 | 66.3\% | 1,240 | 68.1\% | 1,107 | 55.8\% |
| 2017 | 1,186 | 67.9\% | 1,529 | 69.3\% | 891 | 64.1\% | 822 | 67.6\% | 1,254 | 69.3\% | 1,119 | 58.0\% |
| 2018 | 1,199 | 69.1\% | 1,546 | 70.2\% | 901 | 65.3\% | 831 | 68.8\% | 1,268 | 70.6\% | 1,131 | 60.1\% |
| 2019 | 1,212 | 70.4\% | 1,563 | 71.1\% | 911 | 66.6\% | 840 | 70.1\% | 1,282 | 71.8\% | 1,143 | 61.4\% |
| 2020 | 1,225 | 71.6\% | 1,580 | 72.0\% | 921 | 67.8\% | 849 | 71.3\% | 1,296 | 73.1\% | 1,156 | 62.6\% |
| 2021 | 1,238 | 72.9\% | 1,597 | 72.8\% | 931 | 69.1\% | 858 | 72.6\% | 1,310 | 74.3\% | 1,169 | 63.9\% |
| 2022 | 1,252 | 74.1\% | 1,615 | 73.8\% | 941 | 70.3\% | 867 | 73.8\% | 1,324 | 75.6\% | 1,182 | 65.1\% |
| 2023 | 1,266 | 75.4\% | 1,633 | 74.7\% | 951 | 71.6\% | 877 | 75.1\% | 1,339 | 76.8\% | 1,195 | 66.4\% |
| 2024 | 1,280 | 76.6\% | 1,651 | 75.6\% | 961 | 72.8\% | 887 | 76.3\% | 1,354 | 77.2\% | 1,208 | 67.6\% |
| 2025 | 1,294 | 77.0\% | 1,669 | 76.6\% | 972 | 74.1\% | 897 | 76.7\% | 1,369 | 77.6\% | 1,221 | 68.9\% |

In general terms, HNTB expects the following changes to occur over the next 30 years:

- Overall design hour traffic will increase by about $39 \%$.
- At the mainline plazas, the share of ETC traffic will increase by an average of about $22 \%$ over the current average share of $58 \%$.
- At the side toll plazas, where ETC usage during the design hour already averages over $70 \%$, the share of ETC traffic at the side toll plazas will increase by an average of about $10 \%$.

It is important to recognize that, at most toll plazas, the volume of cash-paying traffic will be lower in 2041 than it is today. The trend of declining cash volumes has been observed in recent years and is expected to continue at most locations into the future. The only locations where HNTB expects cash volumes to be higher in 2041 than today are at toll plazas that are already near the expected maximum E-ZPass penetration rate of $80 \%$.

### 6.3 Toll Plaza Capacity Analysis

The final step was to assess the extent to which each toll plaza would be able to handle the projected design-hour demand over the next 30 years. This assessment was based on the following capacities:

Cash-paying vehicles pass through cash lanes at a rate of 325 vehicles per hour (vph). This capacity for cash lanes is a planning-level estimate used by the Authority in determining staffing requirements. In actuality, the capacity is closely tied to the fare that is charged. If cash fares are an even denomination (like the existing rate of $\$ 1.00$ at the side toll plazas), then capacities can be very high, occasionally exceeding 400 vph . On the other hand, if cash fares require the handling of change (such as the $\$ 1.75$ fare currently charged at New Gloucester), then the capacities lie closer to the threshold of 325 vph . The actual capacity can vary throughout the day, based on such factors as the mix of cars vs. trucks and the experience level of the toll attendants.

E-ZPass vehicles pass through dedicated ETC lanes at a rate of $1,150 \mathrm{vph}$. The assumed capacity of dedicated ETC lanes is based on observations of such lanes at various facilities throughout the northeast. The capacity of these lanes-whether at the York toll plaza, at the Saco toll plaza, on the Massachusetts Turnpike, or on the New York State Thruway-is consistently in the range of 1,100$1,200 \mathrm{vph}$.

E-ZPass vehicles pass through cash lanes at a rate of 800 vph . E-ZPass vehicles are currently allowed to drive through cash lanes on the Maine Turnpike. Experience has shown that E-ZPass vehicles do not pass through cash lanes quite as efficiently as they pass through dedicated ETC lanes. Because they are required to repeatedly stop and start again as they mix with cash traffic waiting in the queue, they pass through the cash lanes at a slightly diminished rate of 800 vph .

E-ZPass vehicles pass through open road tolling (ORT) lanes at a rate of $1,800 \mathrm{vph}{ }^{7}$ An ORT lane essentially functions as a regular highway lane. A historical analysis of peak traffic levels on the

[^6]Maine Turnpike suggests that a lane can carry roughly 1,800 vehicles per hour before travel conditions start to significantly deteriorate.

Table 6-5 (mainline plazas) and Table 6-6 (side toll plazas) present a summary of the toll plaza capacity analysis. For each plaza, the following information is provided:

- Configuration. Each column identifies the configuration of the plaza as it is currently operated during peak periods. The exception is New Gloucester, in which we analyzed the configuration that will be in effect after the conversion to ORT is complete. Please note that, as currently designed, vehicles equipped with an E-ZPass are permitted to use cash lanes at all plazas on the Maine Turnpike.
- V/C (volume-to-capacity ratio). If the value in this column is equal to or greater than $100 \%$, then the capacity of the plaza has been exceeded. In such instances, the MTA should consider improving the plaza.
- RC (reserve capacity). This column identifies the number of additional vehicles that the plaza could accommodate before reaching its practical capacity. A negative value indicates that the plaza is operating above its capacity.

The "RC" or "Reserve Capacity" concept is a useful tool for evaluating the impact of developments that may occur in the vicinity of a particular toll plaza. If a development is projected to generate traffic in excess of the Reserve Capacity, then one could consider holding the development partially responsible for expanding (or otherwise improving) the plaza ${ }^{8}$.

In the following two tables, any values that have light shading and bold, black print represent years in which a particular plaza is operating between $90-100 \%$ capacity ${ }^{9}$. Queues start to build during such conditions and can occasionally be lengthy. Values that have dark shading and bold, white print represent years in which a particular plaza is over-capacity; travelers will likely face lengthy peak-hour queues and delays in such conditions. ${ }^{10}$

${ }^{1}$ One of the lanes at the Falmouth Spur Toll Plaza (in each direction) is interchangeable. This analysis is for the lane configuration that is most frequently used. An extra cash lane can be opened if queues develop.

101
Plaza is operating over capacity
99\% Plaza is operating at $90-100 \%$ capacity

The following observations may be drawn from the previous two tables:

- The Falmouth Spur in the entering (WB) direction is the only location that is currently showing to be operating above capacity. However, this is due to the design-hour configuration of the toll plaza. At present, the plaza is usually operated as 1 cash lane and 2 E ZPass lanes. However, the plaza has an interchangeable lane and it can be operated as 2 cash lanes and $1 \mathrm{E}-\mathrm{ZPass}$ lane, which would provide adequate capacity for all customers.
- The Falmouth Spur in the exiting (EB) direction currently operates in excess of $90 \%$ capacity. Again, the plaza has an interchangeable lane and can operate with 2 cash lanes and 1 E-ZPass lane during periods of queuing.
- At the Falmouth Spur (in both the entering and exiting directions), the volume-to-capacity ratio declines over time. In other words, we expect the plaza to operate better in the future as vehicles shift from cash into E-ZPass. In four-to-eight years, as cash volumes diminish, the plaza will operate acceptably with 1 cash lane and 2 E-ZPass lanes during peak periods.
- Two plazas are expected to approach their capacity about 20 years in the future: the 3-lane plaza at Biddeford and the 2-lane plaza at Gray. Neither plaza is expected to exceed its capacity, but both will be operating at above $90 \%$ capacity by 2035. Gray Interchange is currently being studied which may result in moving the southbound ramps and toll plaza to the west side of the Turnpike. Capacity issues at Gray would be addressed if the southbound ramps were re-located.
- One plaza that faces an imminent capacity constraint is the three-lane plaza at Exit 36 in Saco. The plaza currently operates at $95 \%$ capacity, and it will be at its capacity by 2018. There are three avenues for addressing this operational concern:
o Re-analyze this location with an increased share of E-ZPass usage beyond the assumed limit of $80 \% .^{11}$
o Maintain a toll of an even denomination in order to maximize the processing rate.
o Add a dedicated E-ZPass lane at the plaza.

### 6.4 Toll Plaza Analysis - Conclusions and Recommendations

- Three plazas (Biddeford, Scarborough and Gray) are operating at over 75\% capacity and lie in close proximity to a local signalized intersection. Operations at these plazas should be monitored to ensure that the toll plaza operations don't interfere with the flow of traffic on local roads. This will be particularly important at Biddeford and Gray, because these plazas will be operating at $80-90 \%$ capacity during peak periods. Periodic traffic surges at these plazas could result in temporary interference with the local roads ${ }^{12}$. Furthermore, the adjacent signalized intersections may limit the number of vehicles that are able to get to the toll plazas resulting in a lower than forecasted peak hour volume at the toll plaza.
- During peak periods on summer weekends, operate the Falmouth Spur toll plaza with 2 cash lanes and $1 \mathrm{E}-\mathrm{ZPass}$ lane in each direction as needed.

[^9]- Program $\$ 1,420,900^{13}$ for the addition of a dedicated E-ZPass lane at the Saco toll plaza in the year 2018. In the interim, continue to monitor operations as well as traffic growth. If conditions deteriorate, the improvement should be implemented. If conditions stabilize, then construction could be delayed.
- While monitoring operations at Saco, the Authority should consider altering the configuration during weekday peak periods. Providing two dedicated E-ZPass lanes and only one cash lane may improve the flow of traffic. With a cash toll of $\$ 1.00$, a single cash lane with an experienced attendant should be adequate to serve the current cash volume of 300-330 vehicles per hour.
- Use the "Reserve Capacity" calculations to help evaluate the potential effect of developments that may be proposed in close proximity to the Turnpike.

[^10]
## 7 SAFETY CONDITIONS

The safety analysis for this study determined if there are locations with a high crash history, determined if there are measures that can be taken to alleviate the number of crashes, and examined the current safety practices of the Authority and the efficacy of those practices. In addition, HNTB reexamined the safety issues and recommendations identified in the last systemwide traffic operation and safety study and determined the status of those previously identified safety concerns.

All mainline miles, interchanges, ramps and toll plazas on the Maine Turnpike as well as adjacent intersections to the Turnpike were analyzed for this safety analysis. The data used was obtained from MaineDOT: Traffic Engineering, Crash Records Section. The crash study period analyzed is the most recent three year period for which data is available - January 2009 to December 2011.

### 7.1 Crash Rate Comparison

During the 36 month period, a total of 1,922 crashes were recorded on the Turnpike. Of the 1,922 crashes, 965 occurred in the southbound direction of travel while 957 occurred in the northbound direction of travel.

The number of crashes that occur on a roadway is correlated with the amount of traffic on a roadway. In other words, more traffic would generally tend to increase the occurrence of crashes. Similarly, a decline in traffic would generally cause a decrease in the number of crashes. In order to draw comparisons of occurrence of crashes, crash rates are developed, which are the number of crashes divided by the vehicle miles traveled. During the three year period of 2009-2011, there were approximately 52.3 crashes per hundred million vehicle miles traveled on the Turnpike.

For comparison purposes, the same statistics were reviewed from the 2007 systemwide traffic operations and safety study, which analyzed crash data from January 2003 to December 2005. During that time period the crash rate was approximately 58.4 crashes per hundred million vehicle miles traveled. The data shows that the crash rate for the 2009-2011 study period is lower than the crash rate for the 2003-2005 study period.

Data were also gathered on crash rates for the other interstate highways in Maine and the national interstate highways. Figure 7-1 compares the crash rates on the Maine Turnpike with those on Maine's other interstates and the national Interstate System from 2003 through 2010. As can be seen from Figure 7-1, the Turnpike crash rate is lower than the national average crash rate and lower than the other interstate highways in Maine.

Figure 7-1 - Crash Rate Comparison 2003-2010

Note: 2011 crash data was not available for interstates nationwide.

### 7.2 Current Safety Practices

The Authority has implemented many safety practices to promote safe travel along the highway. Those practices include roadside improvement programs, ITS (Intelligent Transportation Systems) upgrades, maintenance practices, and parallel acceleration ramp construction.

## ROADSIDE IMPROVEMENT PROGRAMS

The roadside improvement programs that the Authority is currently undertaking are the following:

- Assessing all median openings for required criteria of sight distance. All openings that do not meet standards are either improved to meet criteria or closed.
- Upgrading all out-of-date guard rail end treatments and adjusting guard rail height where necessary
- Checking all clear zones and increasing distance where practicable. These measures consist mainly of modifying ditching, flattening slopes, and removing ledge. A clear zone study is planned to be conducted this year to identify additional clear zone activities that could be completed cost effectively.

## ITS UPGRADES

The Authority has made the following ITS upgrades since 2006 to promote safe and efficient travel:

- Upgrades to the Highway Advisory Radio (HAR) system; stations have been synchronized and one station was added
- Updates to the Variable Message Sign (VMS) links, controllers, and software which results in greater reliability
- Placement of additional VMS (portable and semi-permanent) along the highway at strategic locations to provide motorists with pertinent travel information
- Upgrades to the email alert system allowing messages to be sent to patrons concerning traffic incidents in a faster, more reliable manner
- Utilization of social media to provide near real-time travel information to patrons
- Upgrades to the Authority's website including enhanced travel information and alerting capabilities
- The installation of two Road Weather Information Systems (RWIS) in Saco and Gray which alerts maintenance crews of winter weather situations and decreases crew response times
- Utilization of five additional Closed Circuit Television systems (CCTV) for incident detection and verification. One system was installed in Biddeford, another in Gray and the three remaining systems are portable.

## ACCELERATION LANES

Over the past few years, the Authority has focused on converting taper lanes to parallel type lanes. This generally gives patrons a longer merge area and, in turn, more time to make a safe merge maneuver. The following are examples of lanes that have been converted:

- Exit 75 NB was completed in 2012
- Exit 75 SB is currently under construction and due to open later in 2012
- Exit 45 NB is currently under construction
- Exit 45 SB is currently under construction
- Exit 48 NB acceleration lane was extended in 2011
- Exit 48 SB acceleration lane was extended in 2011
- Exit 53 NB acceleration lane is currently under construction and will be open by the end of 2012
- Exit 52 NB was opened in 2011
- MaineDOT extended the acceleration lane at Exit 109 SB in $2011^{14}$. This location was identified as a high crash location in the previous systemwide traffic operations and safety study.

## MAINTENANCE PRACTICES

In addition to these programs, standard maintenance measures are constantly undertaken to improve traveling conditions and, in turn, safety conditions along the length of the Turnpike. Examples of these regular maintenance practices are:

- Re-striping all lines bi-annually
- Repairing pot-holes and filling cracks between scheduled resurfacing projects
- Regularly cleaning/maintaining storm drainage systems
- Pre-treating the roadway before major winter storms
- Sweeping excess sand from the roadway during the spring months
- Selectively choosing when to allow lane closures for both construction and maintenance activities so that the impact on traffic flow is minimal
- Keeping shoulder areas cleared of trash and debris
- Mowing side slopes to increase visibility
- Repairing guardrail as soon as possible following crash damage
- Providing a night patrol to monitor the highway and notify crews of dangerous driving conditions

[^11]- Coordinating with two Traffic Incident Management Committees to improve safety for responders and motorists while minimizing the impact incidents have on the normal flow of traffic
- Maintaining 60 inch Yield signs at every entry ramp
- Reviewing and adding additional Wrong Way signs at off-ramps when appropriate

### 7.3 Current Safety Studies

The Authority has recently conducted several studies regarding safety issues. Those studies deal with overheight vehicles and improvements to mainline toll plazas, which historically have been high crash locations.

## OVERLIMIT VEHICLES

HNTB Corporation completed a study in 2007 looking at the policies of overlimit vehicles (defined as any vehicle that exceeds regulations for width, height, length, or weight) of the Turnpike. Overlimit vehicles present a few safety issues. Some overlimit vehicles are not able to maintain the posted minimum speed of 45 MPH on the Turnpike. Overwidth vehicles sometimes are forced to occupy a second travel lane because law enforcement and disabled vehicles preclude the use of the shoulder. Another concern is that there is limited storage area at Turnpike toll plazas for overlimit vehicles that are waiting to enter the Turnpike. The Authority restricts entry due to weather, time of day, and other regulations specific to overlimit vehicle travel. Overheight vehicles can create another problem-structural damage to bridges. Overheight vehicles have hit Turnpike bridges in the past and have caused significant structural damage. Structurally damaged bridges present a safety concern.

The following conclusions were drawn from the overlimit study:

- The Maine Turnpike Authority is continuing their current policy of:
o Building new bridges with $16^{\prime} 6^{\prime \prime}$ clearance, and increasing clearance on existing bridges to a minimum of $15^{\prime} 0^{\prime}$ as part of major rehabs.
0 Constructing new toll plazas with $16^{\prime}-6^{\prime \prime}+/-$ of clearance and maintaining a clear roadway width of $16^{\prime}-0^{\prime \prime}$ in wide load lanes
- The Authority identified a limited number of locations for targeted over-height detection systems, at entry points upstream of structures most prone to vehicle strikes.
- The Authority continues to endorse the BMV's policy to route all possible overlimit vehicles onto the Maine Turnpike rather than local roadways.
- The Authority did not bifurcate the system relative to overlimit regulations.

In 2011, an overheight vehicle detector system was installed on the local road on each side of the Warren Avenue overpass. Signs and flashing beacons alert drivers if their vehicle is too high to safely pass under the Warren Avenue overpass. A similar system has been proposed in the near future for Auburn (Exit 75) and West Gardiner (Exit 103) to alert overheight vehicle drivers to not enter the Turnpike.

## WEST GARDINER INTERSECTION STUDY

The stop controlled 4 -way intersection of Exit 102, Lewiston Road (Routes 9/126) and the West Gardiner service plaza driveway was the high crash location (HCL) with the highest crash rate in the
state during the 2009-2011 study period. Twenty-five crashes occurred at this location in the three year period and the crash rate factor (CRF) is reported as 19.91. This indicates that crashes occur at this location at approximately 20 times as much as similar locations in the state over the three year reporting period. Twenty-three of the twenty-five crashes at the location were angle crashes. Due to the severity of these ratings a signal warrant analysis was completed in February 2012 by HNTB Corporation. A traffic signal warrant was met for this location, in accordance with the guidelines set forth in the MUTCD, ${ }^{15}$ and a signal was recommended in a memorandum addressed to the Authority dated February $21^{\text {st }}, 2012$. However, meeting a traffic signal warrant does not in itself justify a signal. A meeting was held with MaineDOT. During that meeting, MaineDOT recommended changes to the pavement markings, including re-positioning the stop bars, as a method to improve the safety at this location. As a result, the Authority has implemented the pavement marking recommendations.

## NEW GLOUCESTER ORT CONVERSION

The Authority is currently in the process of converting the New Gloucester toll plaza to allow for open road tolling (ORT). The project involves the removal of the four middle toll lanes at the plaza and replacing them with one highway speed ORT E-ZPass Only lane in each direction. These ORT lanes will include concrete barrier walls separating each direction as well as separation from the remaining cash toll lanes. Customers with E-ZPass will no longer be required to slow down or stop at the toll plaza. These customers will be able to use specially designed barrier separated toll lanes for non-stop tolling as shown in Figure 7-2

Figure 7-2 - ORT Tolling Layout

Once completed, the New Gloucester toll plaza ORT conversion will provide multiple safety improvements. With roughly half of the transactions at the plaza paid via E-ZPass, the potential for reducing traffic crashes at the plaza is significant. On approach to the toll plaza, the driver is directed to select either the ORT or cash side of the plaza well in advance of the plaza itself. From a traffic operations and crash potential perspective, these plazas are more akin to a highway split or interchange ramp than a traditional toll plaza. The result is a reduction in conflicts between vehicles of differing speeds and reduced weaving in the cash lanes related to lane changing. Based on historical data reported by major facility conversions to ORT in states such as Florida, New Jersey,

[^12]Texas and Illinois, crashes have been reduced by as much as $50-60 \%$. Therefore ORT has significant opportunity to improve the safety of the traveling public.

In addition to reducing vehicle crashes at the toll plaza, ORT will also reduce the exposure of toll collectors to non-stop traffic and total traffic in general. Toll collectors will continue to have the benefit of the tunnel to access the plaza. In some cases, the safety of the tunnel will be the only means of access since the ORT lanes will eliminate the option for collectors to cross the entire plaza at the roadway level to access toll lanes. A reduction in exposure to cash traffic coupled with virtual elimination of exposure to E-ZPass traffic will improve the safety of toll collectors.

## YORK TOLL STUDY

In June, 2010 HNTB Corporation summarized the safety and capacity issues at the York Toll plaza in the report titled "Maine Turnpike - Southern Toll Plaza" at the request of the Authority. The document stated:
"The York Toll Plaza began as a temporary 11-lane structure constructed on the Turnpike in York, Maine in 1969 as part of the continuation of Interstate 95 and the construction of the Piscataqua River Bridge. Numerous maintenance and rehabilitation projects have been undertaken to improve the capacity of the plaza, to cope with its aging components, and to provide safety for both the traveling public and toll plaza staff. However, the ongoing maintenance and rehabilitation projects can no longer effectively keep up with the York Toll Plaza's deterioration; its life expectancy has been exceeded and it is no longer able to provide adequate safety for staff or the millions of vehicles that pass through it each year, nor is it able to provide for efficient traffic operations."

There are a number of operational issues related to the plaza's location that seriously affect safety of patrons and staff and require attention:

1) The plaza is located 500 to 700 feet north of the Exit 7 Interchange, causing additional merging and weaving of traffic within the plaza limits. This also leads to an inefficient use of toll lanes, causing traffic back-ups before the plaza has reached capacity volumes.
2) The plaza is on a horizontal curve. Southbound traffic tends to drift to the outside of the curve, reducing utilization of all tollbooths, i.e. left side lanes become over-utilized and right side lanes underutilized. The curve also blocks sight to all southbound lanes/tollbooths until an approaching vehicle is approximately 1,500 feet away. This does not allow adequate time to make efficient lane choice decisions and can cause sudden unsafe lane changes.
3) The plaza is at the base of a hill. This creates a safety concern due to the potential of heavy vehicles losing their brakes and striking the plaza or stopped traffic, drainage issues, and pavement "shoving", leading to excess rutting and the potential for hydroplaning. The hill also leads to heavy engine braking noise southbound and heavy acceleration noise northbound as commercial vehicles negotiate the only truck climbing lane on the Turnpike.
4) The plaza is approximately 2,200 feet north of the Chases Pond Road Bridge over the Turnpike. This bridge essentially hides the merging on-ramp traffic at Exit 7 from view of northbound travelers, and reduces visibility of traffic queues at the toll booths. A driver's ability to adequately comprehend (and react to) roadway signage is also compromised due to a need to sign for both the toll plaza and the interchange within a very short distance. The
proximity of the toll plaza and interchange requires double the number of signs at less than desirable spacing.

All four of these characteristics; nearby interchange, roadway curve, bottom of a hill, and nearby bridge contribute to increased crashes and decreased operational efficiency. This has led to the south side of the toll plaza, either the northbound or southbound lanes, or both, to be classified as High Crash Locations for the last 10 years by MaineDOT.

The Authority is currently reviewing the York Toll Study.

### 7.4 Other Studies

The Authority has also recently conducted several studies regarding mobility and safety issues. Those studies deal with improvements to some of the intersections adjacent to the Turnpike as well as future transportation needs in identified corridors.

## EXIT 75 STUDY

HNTB Corporation studied the Exit 75 (Auburn) interchange and presented results in a two phase report. Phase I was published in December 2009 and identified short term transportation needs. Phase II was published in March 2010 and identified long term transportation needs.

Phase I investigated concerns regarding the interchange and the surrounding area which were raised by local residents and officials. These concerns included:

- The condition of the pavement and adequacy of signing
- Difficult traffic maneuvers due to the limited distance for traffic weaving patterns combined with the high number of heavy trucks that use the interchange
- The overall condition/appearance of the interchange

Based on a condition assessment and comparison, the following improvements were recommended in Phase I at Exit 75:

- Paving
- Installation of guide signs
- Moving guardrail/edge of pavement
- Removing the existing utility building.

These improvements were approved by the Authority and have been implemented.

Phase II evaluated the future transportation needs of the Exit 75 study area as well as the needs of Greater Auburn. Six different build alternatives were evaluated based on their ability to reduce the expected traffic congestion, estimated cost to implement, and potential right-of-way impacts.

Based on the analysis and evaluation conducted in the Phase II Study, the following improvements were recommended:

- Exit 75 at Route 202/4/100. Widen the Route 202/4/100 northbound approach to accommodate two left turn lanes for traffic heading toward the Turnpike
- Route $202 / 4 / 100$ at Kittyhawk Avenue. Widen the Route 202/4/100 northbound approach to accommodate a left turn lane of 150 foot length for traffic heading onto Kittyhawk Avenue and an additional shared through/right lane of 200 feet
- Route 202/4/100 at Kittyhawk Avenue. Widen the Route 202/4/100 southbound approach to accommodate a 150 foot channelized right turn lane for traffic heading onto Kittyhawk Avenue
- Route 202/4/100 at Kittyhawk Avenue. Widen the eastbound Kittyhawk Avenue approach to accommodate two left turn lanes of 550 foot length for traffic heading north on Route 202/4/100

HNTB has completed preliminary design of the improvements. The Authority is coordinating with MaineDOT regarding funding for the improvements.

## WEST GARDINER AND GARDINER I-295 DRAFT TOLL STUDY

On July 31, 2012 HNTB Corporation published the ‘Gardiner/West Gardiner Toll Plaza Replacement Study' for the Authority. This study documented the feasibility of and options for replacement or rehabilitation of the existing West Gardiner and Gardiner I-295 toll plazas. HNTB Corporation evaluated the following options:

- Option 1: Combining the West Gardiner and Gardiner I-295 toll plazas at a location north of Mile 103.
- Option 2: Upgrade the Gardiner I-295 toll plaza in current location without Open Road Tolling (ORT) and upgrade West Gardiner toll plaza to ORT.
- Option 3: Relocation of the Gardiner I-295 toll plaza to accommodate ORT (2 ramp toll plazas) and upgrade West Gardiner toll plaza to ORT.
- Option 4: Maintain the Gardiner I-295 toll plaza with limited improvements (No new toll lanes for capacity enhancements) and upgrade West Gardiner toll plaza to ORT.

The Authority is currently reviewing the West Gardiner and Gardiner I-295 Toll Study.

## GORHAM EAST-WEST CORRIDOR FEASIBILITY STUDY

The purpose of this study was to develop a series of recommendations to enhance, expand, and preserve highway connections between Route 1 and the Maine Turnpike and communities in western Cumberland County. This study focused on the effects that land use has on transportation and developed a coordinated land use, transit, and highway improvement strategy to reduce future demand on the regional transportation network.

The Phase I Study and Report was completed in October 2012. The Authority and MaineDOT are working together to develop the scope of a Phase II study, which is anticipated to begin in the Spring of 2013 pending approval of the Turnpike Authority Board. Results of this study could result in a new connection to the Turnpike, which will have an impact on future traffic estimates in the Portland area.

## CENTRAL YORK COUNTY CONNECTIONS STUDY

The MaineDOT and the Authority are currently evaluating strategies to improve mobility between central York County and the coastal highways of Route 1 and the Maine Turnpike. The purpose of
the Central York County Connections Study is to identify, evaluate, and recommend feasible transportation and related land use strategies that will:

- enhance regional economic growth
- increase regional transportation interconnectivity
- improve traffic safety
- direct expected travel demand through a strong mix of multimodal strategies
- preserve and improve existing infrastructure

In addition, it is a goal of the study to strive to maintain the visual, cultural, and historic character of the study area and minimize environmental impacts.

### 7.5 High Crash Locations

MaineDOT has a system of classifying whether or not a particular roadway location is considered a high-crash location (HCL). MaineDOT's Crash Records Section summarizes all reported crashes in which there is property damage in excess of $\$ 1000$, or in which there has been personal injury. In order to summarize this information, the MaineDOT has established a Node and Element System. This system assigns a four or five-digit node number to each intersection, major bridge, railroad crossing, and crossing of town, county, or urban compact lines as a node. The segments of road that connect the nodes are referred to as elements. As crash reports are received by MaineDOT, the information is assigned to the corresponding element or node at which they occurred.

A designation of HCL warrants an analysis for patterns of crashes associated with possible geometric issues. If crash history of a particular element or node meets two criteria, then MaineDOT would classify it as a high-crash location (HCL). The criteria are:

- The element or node must have eight or more reported crashes over the past three years
- The element or node must have a "critical rate factor" (CRF) greater than 1.00. (The critical rate factor relates the crash rate at a particular element or node to the statewide crash rate average for a similar type of facility ${ }^{16}$.

The previous systemwide traffic operations and safety study identified all of the high crash locations on the mainline of the Turnpike. This study identifies not only the mainline segments, but also the ramps and the intersections adjacent to the Turnpike which are HCLs. The following sections show how the mainline HCLs have changed in the past 6 years and provide an analysis for the current HCLs.

[^13]
### 7.5.1 High Crash Locations 2003-2005 Update

Table 7-1 lists the high crash locations on the Turnpike mainline for the period 2003-2005. This was the period studied in the previous systemwide traffic operations and safety study published in 2007.

Table 7-1 - 2003-2005 HCLs on Mainline

|  | Town | Description | Crashes | CRF |
| :--- | :--- | :--- | :--- | :--- |
| Toll Plaza Node | York | North of York Interchange near Toll Plaza | 18 | 4.45 |
|  | Wells | North of Wells Interchange | 13 | 1.20 |
|  | Biddeford | South of Biddeford Interchange | 10 | 1.75 |
|  | Portland | South of Rand Road Interchange | 8 | 1.30 |
|  | Cumberland | North of Falmouth /Cumberland Town Line | 22 | 1.01 |
|  | Gray | South of Gray Interchange | 23 | 1.03 |
|  | Gray | North of Gray Interchange | 14 | 1.01 |
|  | New Gloucester | North of New Gloucester/Gray Town Line near Toll Plaza | 11 | 1.33 |
|  | Saco | North of Biddeford/Saco Town Line | 16 | 1.04 |
|  | New Gloucester | North of New Gloucester/Gray Town Line near Toll Plaza | 13 | 1.52 |
|  | Augusta | North of Augusta/Hallowell Town Line at Merge Area | 16 | 1.37 |

Each of the 2003-2005 HCLs will be discussed briefly to review the recommendations that were made previously and the current status of those locations.

## 1. North of the York Interchange NB, York

Original Recommendation: It was expected that a potential increase in E-ZPass usage at the plaza would help to reduce crash rates.

Status: York Barrier Toll plaza is still an HCL, but now in both the northbound and southbound directions south of the Barrier Toll plaza.

## 2. North of the Wells Interchange in the NB Lanes - Mile 19

Original Recommendation: Given the fact that there were a large number of coincidental occurrences and no obvious physical problems at this location, HNTB Corporation recommended watching this site in the future to see if the problem persisted or if this particular site was an anomaly.

Status: This location is still an HCL and will be discussed further in this study.
3. South of the Biddeford Interchange in the NB Lanes - Mile 31

Original Recommendation: Since $50 \%$ of the crashes at this location were due to drivers making unsafe lane changes or operating vehicles at illegal and unsafe speeds, HNTB Corporation recommended that this location be reviewed with the state police for further evaluation.

Status: This location is no longer an HCL.

## 4. North of the Biddeford/Saco town line in the SB Lanes - Mile 33

Original Recommendation: Seventy-five\% of the crashes at this location occurred when road conditions were classified as wet, snow, or ice. HNTB Corporation recommended that a pavement sensor be installed to alert Turnpike staff of freezing conditions at this location.

Status: A pavement sensor was installed. This location is no longer an HCL.

## 5. South of the Rand Road Interchange in the NB Lanes - Mile 47

Original Recommendation: During the 2003-2005 study period this interchange was quite new; having just been completed in December of 2002. Some crashes were suspected to have been caused by driver unfamiliarity. HNTB Corporation recommended watching this site in the future to see if the problem persisted.

Status: This location is no longer an HCL.

## 6. North of the Falmouth/Cumberland town line in the NB Lanes - Mile 57

Original Recommendation: At this location the highway ascends up a fairly long, steep incline known as 'Morrison Hill'. Forty percent of the total crashes were related to poor weather conditions. HNTB Corporation recommended additional signing in this area to warn drivers of the potentially dangerous conditions during inclement weather.

Status: This location is no longer an HCL.

## 7. South of the Gray Interchange in the NB Lanes - Mile 62

Original Recommendation: Almost $70 \%$ of crashes at this location were related to poor weather conditions and $48 \%$ of crashes occurred during snow or ice conditions. During the winter months this section of the roadway remains very shaded during the morning daylight hours due to high embankments. HNTB Corporation recommended applying anti-icing solution prior to snowstorms and installation of a pavement sensor which could alert Turnpike staff of freezing conditions when precipitation is not present.

Status: A pavement sensor was installed. This location is no longer an HCL.

## 8. North of the Gray Interchange in the NB Lanes - Mile 63

Original Recommendation: Fifty percent of all crashes at this location were related to poor weather conditions and $21 \%$ of all crashes occurred during snow/ice conditions. HNTB Corporation recommended applying anti-icing solution prior to snowstorms and installation of a pavement sensor which could alert Turnpike staff of freezing conditions when precipitation is not present.

Status: A pavement sensor was not installed at this location. However, a pavement sensor was installed south of the interchanges (mentioned previously). This location is no longer an HCL.

## 9. North of the New Gloucester/Gray town line in the NB Lanes - Mile 66

Original Recommendation: It was expected that a potential increase in E-ZPass usage at the New Gloucester Toll Plaza would help to reduce crash rates. Toll plazas commonly experience high crash rates due to the disruption to traffic flow. Also, the MTA had planned to test 'E-ZPass purple' pavement markings at this location to make E-ZPass lanes more noticeable.

Status: This location is still an HCL and will be discussed further in this study.

## 10. North of the New Gloucester/Gray town line in the SB Lanes - Mile 66

Original Recommendation: It was expected that a potential increase in E-ZPass usage at the New Gloucester Toll Plaza would help to reduce crash rates. Toll plazas commonly experience high crash rates due to the disruption to traffic flow. Also, the MTA had planned to test 'E-ZPass purple' pavement markings at this location to make E-ZPass lanes more noticeable.

Status: This location is still an HCL and will be discussed further in this study.

## 11. North of the Augusta/Hallowell town line in the SB Lanes - Mile 108

Original Recommendation: While no obvious geometric flaw or other cause (i.e. weather) could be identified at this merge area, HNTB Corporation recommended watching this site in future years to see if it continued to be classified as an HCL and if a pattern developed.

Status: This location is no longer an HCL.

### 7.5.2 Current High Crash Locations of the Maine Turnpike and Ramp Intersections

This safety analysis examined the crash data of designated high crash locations to determine patterns and potential remedies. According to the most recent MaineDOT data available which dates from January 2009 through December 2011 there are nine areas classified as HCLs on the Turnpike mainline. The northbound travel lane has three HCLs while the southbound travel lane has six. An additional five entry and exit ramp locations and four intersections with local roads were identified as HCLs. Recommendations for safety improvements are presented; however, costs for the improvements were not estimated.

## HIGH CRASH LOCATIONS - MAINLINE SEGMENTS

Table 7-2 shows a summary of the Turnpike mainline segments that are currently considered high crash locations. Each high crash location of the mainline is discussed in the following paragraphs.

Table 7-2 - 2009-2011 HCLs on Mainline

|  | Town | Node/Element | Description | Crashes | CRF |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Toll Plaza Nodes | York | 57692 | Mile post 7.13 - NB approach to York Barrier Toll plaza | 11 | 3.73 |
|  | York | 57693 | Mile post 7.13 - SB approach to York Barrier Toll plaza | 10 | 3.36 |
| NB segments | Wells | 239695 | Exit 19 NB merge area to Burnt Mill Rd | 10 | 1.04 |
|  | Gray | 195030 | 0.5 miles from New Gloucester Barrier Toll plaza to Mayall Rd. | 9 | 1.29 |
| SB segments | West Gardiner | 2524169 | 0.78 miles from High Street to West Gardiner/Farmingdale TL | 17 | 1.24 |
|  | New Gloucester | 2523347 | 0.84 miles from Shaker Road to Bald Hill Road | 11 | 1.03 |
|  | New Gloucester | 2523359 | 1.14 miles from Mayall Road to Bennett Road | 17 | 1.25 |
|  | New Gloucester | 2523361 | 0.48 miles from New Gloucester Barrier Toll plaza to Mayall Rd. | 13 | 1.86 |
|  | York | 2522897 | York Barrier Toll Plaza to York Interchange | 10 | 2.38 |

A few facts to note about the data in Table 7-2 are:

- The southbound mainline direction has more than twice as many HCLs as the northbound direction
- The York Barrier Toll plaza and adjacent sections make up three of the nine HCLs and have the highest CRF ratings.

## 1. York Interchange to York Barrier Toll plaza in the NB Lanes - Mile 7

This brief section of highway encompasses the area from the York interchange to the York Barrier Toll plaza. The types of crashes recorded are similar at most toll plazas where mainline traffic flow is interrupted: two crashes were classified as rear ends, two crashes were backing, two crashes sideswipes, four crashes involved a fixed object, and one crash a driver lost control. The close proximity of the barrier toll plaza to the York interchange contributes to lane change issues by adding another stream of traffic flow accessing lanes to the plaza over a short distance.

The area between the York Barrier Toll Plaza and the York interchange has been a high crash location for a number of years. Improvements to the York toll plaza are currently being considered, including the possibility of rebuilding the York toll plaza as an ORT facility.
Total number of crashes: 11, CRF: 3.73

## 2. Approach to the York Barrier Toll Plaza in the SB Lanes - Mile 7

This brief section of highway is the approach to the York Barrier Toll Plaza. The types of crashes recorded are similar at most toll plazas where mainline traffic flow is interrupted: six crashes were classified as rear ends, two crashes were sideswipes and two crashes involved a fixed object. The geometry at this location is not ideal. The toll plaza is on a curve at the bottom of an incline.

The area between the York Barrier Toll Plaza and the York interchange has been a high crash location for a number of years. Improvements to the York toll plaza are currently being considered, including the possibility of rebuilding the York toll plaza as an ORT facility.
Total number of crashes: 10, CRF: 3.36

## 3. York Barrier Toll plaza to York Interchange in the SB Lanes - Mile 7

This 0.11 mile section of highway is on the departing side of the York Barrier Toll plaza to the SB Off ramp at the York interchange. The most common type of crash (five of ten) was sideswipes as drivers try to merge into three departing lanes. The other types of crashes were one rear-end, two off-theroad, one rollover, and one vehicle fire. The close proximity of this York Barrier Toll plaza to the York interchange contributes to the lane change issues by forcing exiting traffic to move to the rightmost lane in a short distance after exiting the York Barrier Toll plaza.

Advanced overhead signing with a clear message about which plaza lanes are best to use for accessing York interchange may help to improve traffic flow at this location. The area surrounding the York Barrier Toll Plaza has been a high crash location for a number of years. Improvements to the York toll plaza are currently being considered, including the possibility of rebuilding the York toll plaza as an ORT facility.
Total number of crashes: 10, CRF: 2.38

## 4. North of the Wells Interchange in the NB Lanes - Mile 19

This area, 0.32 miles in length, is a typical merge section in the southern region of the Turnpike; the on ramp merges with a three lane mainline. Five of the ten crashes occurred during inclement weather conditions. Crash types varied considerably: four of the crashes were classified as ran off road, two were animal hits, two were fixed object hits, one was a sideswipe and one was a rollover. Despite no obvious physical problems at this location it was also ranked as an HCL in the last systemwide traffic operations and safety study covering 2003-2005 data.

It may be beneficial for maintenance to pay particular attention to this area during inclement weather conditions. This would also be a reasonable location to consider for installation of a pavement sensor which could alert Turnpike staff of freezing conditions when precipitation is not present. Also, the northbound acceleration lane is a taper lane. This location would be a reasonable location to convert from a taper to a parallel acceleration lane. The Authority has converted taper lanes to parallel acceleration lanes at other locations on the Turnpike. A parallel lane generally gives patrons a longer merge area and, in turn, more time to make a safe merge maneuver.
Total number of crashes: 10, CRF: 1.04

## 5. New Gloucester Barrier plaza to Mayall Road in the NB Lanes - Mile 66

This section is a 0.50 mile area just south of the New Gloucester Barrier Toll Plaza. Toll plazas commonly experience high crash rates due to the disruption to mainline traffic flow. The crash types recorded were: two sideswipes, two backing, three hitting fixed objects, and two ran-off-road crashes.

The New Gloucester Barrier plaza is currently being modified and will operate as an Open Road Tolling facility with one highway speed lane in each direction and a barrier separated traditional plaza for cash paying patrons. It is expected that this facility change will reduce the crashes occurring at this location.
Total number of crashes: 9, CRF: 1.29

## 6. New Gloucester Barrier plaza to Mayall Rd in SB Lanes - Mile 67

This section is a 0.48 mile area from Mayall Road to the New Gloucester Barrier Toll Plaza. The types of crashes recorded were similar at most toll plazas where mainline traffic flow is interrupted: seven
crashes were classified as 'rear ends', two crashes were sideswipes and two crashes involved an animal (deer) collision.

The New Gloucester Barrier plaza is currently being modified and will operate as an Open Road Tolling facility with one highway speed lane in each direction and a barrier separated traditional plaza for cash paying patrons. It is expected that this facility change will reduce the crashes occurring at this location.
Total number of crashes: 13, CRF: 1.86

## 7. North of Mayall Road to Bennett Road in the SB Lanes - Mile 68

This section encompasses a 1.14 mile long section of highway north of the New Gloucester Barrier Toll plaza. Four drivers noted they were distracted, merging or slowing for traffic due to the New Gloucester Barrier Toll plaza. Six crashes occurred during inclement weather conditions and four of these six drivers were noted as exceeding the posted speed limit or driving too fast for the inclement weather conditions. Nine of the crashes involved vehicles that went off of the road, three were rear-end/side-swipe, three crashes were animal collisions (two moose and one deer), and two of the collisions involved hitting objects in the road.

It is expected that modification to the New Gloucester Barrier Toll plaza will reduce the number of crashes at this location. This would also be a reasonable location to consider for installation of a pavement sensor which could alert Turnpike staff of freezing conditions when precipitation is not present. It may also be beneficial to review this location with the state police for further evaluation, specifically during inclement weather.
Total number of crashes: 17, CRF: 1.25

## 8. North of Shaker Road to Bald Hill Road in the SB Lanes - Mile 71

This 0.84 mile section of roadway is fairly straight and has a bridge over one waterway; the Royal River Reserve. Four of the eleven crashes at this location occurred during snow or ice conditions. Five of the crashes were vehicles that went off the road, four crashes were collisions with deer, one crash involved a vehicle hitting an object in the road, and one crash was a sideswipe.

It may be beneficial for maintenance to pay particular attention to this area during inclement weather conditions. Two W11-3 (Deer) warning signs could also be installed on either side of the roadway in advance of this area.
Total number of crashes: 11, CRF: 1.03

## 9. North of High Street to W. Gardiner/Farmingdale town line in the SB Lanes - Mile 104

Fourteen of the seventeen crashes at this 0.78 mile roadway section occurred when the roadway was classified as 'wet' during a rain event. Hydroplaning was also mentioned in the crash descriptions numerous times. The evidence suggests that water pooling in the wheel ruts is a contributing factor to the majority of the crashes along this highway section.

Resurfacing of this section of highway is planned for 2014. The resurfacing would eliminate the wheel ruts and should reduce the crashes along this highway segment.
Total number of crashes: 17, CRF: 1.24

The detailed collision diagrams for each of these mainline locations can be found in Appendix E. These diagrams provide extensive details concerning each crash that occurs at these high crash locations.

## HIGH CRASH LOCATIONS - TURNPIKE RAMPS

Table 7-3 shows a summary of the Turnpike ramps that are currently considered high crash locations. Each high crash ramp is discussed in the following paragraphs.

Table 7-3-2009-2011 HCLs on Turnpike Entrance and Exit Ramps

| Town | Node/Element | Description | Crashes | CRF |
| :--- | :---: | :--- | :---: | :---: |
| Wells | 239745 | 0.27 miles, Exit 19 SB Off Ramp | 8 | 3.71 |
| Kennebunk | 239756 | 0.51 miles, Exit 25 SB Off Ramp | 9 | 2.57 |
| Biddeford | 239715 | 0.13 miles from local street (toll plaza), <br> Exit 32 On Ramp | 8 | 1.62 |
| Falmouth | 2036928 | 0.17 miles from local street (toll plaza), <br> Exit 53 On Ramp | 8 | 2.00 |
| Portland | 2836952 | 0.07 miles from local street (toll plaza), <br> Exit 48 Off Ramp | 8 | 2.92 |

## 1. Exit 19 SB Off Ramp, Wells

This section of the Exit 19 southbound off-ramp is 0.27 miles long. Half of the crashes at this location (four of eight) were caused by asleep or fatigued drivers. Seven of the eight crashes were classified as 'went off road' and one classified as a vehicle fire. No apparent geometric reasons for these types of crashes were found during an on-site investigation.

While not standard on Turnpike entrance and exit ramps, it is recommended that Sonic Nap Alert Patterns (SNAPS) be installed at this location. The addition of SNAPS on the shoulders of the exit ramp may reduce the number of crashes due to fatigued drivers or driver inattention.
Total number of crashes: 8, CRF: 3.71

## 2. Exit 25 SB Off Ramp, Kennebunk

This section of the Exit 25 southbound off-ramp is 0.51 miles long. This ramp accesses both a service plaza and local roadways. The ramp splits after 120 feet leaving a very short distance for drivers to decide which direction they want to travel. Eight of the nine crashes on the ramp were caused by drivers backing up with the other crash being a sideswipe. This is most likely due to driver unfamiliarity and the need for quick decision making.

This service plaza/Kennebunk exit area contains both a Service Plaza ramp and a ramp for Exit 25 which may be confusing for the unfamiliar motorist. Changes to the guide signs may help. It is recommended that the guide signs at this exit be reviewed for effectiveness and clarity.
Total number of crashes: 9, CRF: 2.57

## 3. Exit 32 Ramps, Biddeford

This section is described as the Exit 32 ramps from the intersection with the local road for a distance of 0.13 miles. This covers both entering and exiting directions of traffic. Crashes in this location vary considerably: three crashes are on the exiting ramp and five are on the entering ramp. Two crashes were classified as hitting a fixed object; three were sideswipes; one was backing, one was a rear-end and one was classified as head on. All crashes occurred during clear weather conditions and seven of the eight crashes occurred while the roadway was dry.

There is no obvious crash pattern or other cause (e.g. weather) identified at this HCL. HNTB Corporation recommends monitoring this ramp in future years to see if it continues to be classified as a HCL and if a pattern develops. If so it may become necessary to conduct a more detailed safety assessment to identify safety-related improvements.
Total number of crashes: 8, CRF: 1.62

## 4. Exit 48 Ramps, Westbrook

This section is described as the Exit 48 ramps from the intersection with the local road for a distance of 0.07 miles. This covers both entering and exiting directions of traffic. The types of crashes recorded were similar at most toll plazas where traffic flow is interrupted: Two crashes classified as rear ends, four crashes were sideswipes, one crash was due to backing and one crash involved a fixed object. The decision making distance between the intersection with the local road and the toll plaza is very short (less than $1 / 10$ of a mile) which likely leads to confusion, braking and rear end/sideswipe collisions at this location.

Improved advanced signing on all legs of the intersection with the local road could help to improve safety by encouraging unfamiliar drivers to choose the correct lane well in advance. Improved lane striping in the decision making area between the intersection and the toll plaza may also help.
Total number of crashes: 8, CRF: 2.92

## 5. Exit 53 Ramps, West Falmouth

This section is described as the Exit 53 ramps from the intersection with the local road for a distance of 0.17 miles. This covers both entering and exiting directions of traffic. Crashes in this location vary considerably: three crashes are on the exiting ramp while five are on the entering ramp. Two crashes were classified as hitting a fixed object; four were sideswipes; one was backing and one was a 'rearend'. Two crashes occurred during rainy weather, the rest during clear weather conditions.

There is no obvious crash pattern or other cause (e.g. weather) identified at this HCL. The interchange bridge serving southbound traffic over the Turnpike is currently being rehabilitated.

HNTB Corporation recommends monitoring this ramp in future years to see if it continues to be classified as an HCL and if a pattern develops. If so it may become necessary to conduct a more detailed safety assessment to identify safety related improvements.
Total number of crashes: 8, CRF: 2.00

The detailed collision diagrams for each of these locations can be found in Appendix F. These diagrams provide extensive details concerning each crash that occurs at these high crash locations.

## HIGH CRASH LOCATIONS - LOCAL INTERSECTIONS ADJACENT TO THE TURNPIKE

Table 7-4 shows a summary of the local intersections adjacent to the Turnpike that are considered high crash locations. These intersections are not the jurisdiction of the Authority nor does the Authority assume any responsibility for them. The information on intersections where the Authority connects to local roads or state highways is provided as part of this study so the Authority can assess issues and determine impacts that improvements on Turnpike may have on adjacent roadways. With this information the Authority can plan accordingly and coordinate improvements, where appropriate, with communities and the Maine Department of Transportation. The exception to this would be the intersection of Exit 102 and Rt. 126 in West Gardiner where the Authority built a Service Plaza and assumes some responsibility for the intersection as a condition of the traffic movement permit.

Table 7-4-2009-2011 HCLs at local intersections adjacent to the Turnpike

| Towns | Node/Element | Description | Crashes | CRF |
| :--- | :---: | :--- | ---: | ---: |
| Kittery | 58964 | Interchange: Exit 2 Off Ramp \& Rodgers Road | 11 | 2.42 |
| Wells | 58365 | Interchange: Exit 19 Off Ramp \& Sanford Road | 19 | 1.09 |
| Portland | 18670 | Interchange: Exit 48 Off Ramp \& Riverside Street <br> \& Larrabee Road | 52 | 1.91 |
| W. Gardiner | 28516 | Interchange: Exit 102 Ramps \& Routes 9/126 | 25 | 19.91 |

Notes regarding this data are:

- The highest number of crashes (52) occurred at the intersection of Exit 48 and Riverside Street/Larrabee Road. This location experienced more than twice as many crashes as the other high crash intersections that are adjacent to the Turnpike.
- The CRF at the intersection of Exit 102 and Routes $9 / 126$ is 19.91 . This location is ranked \#1 by MaineDOT as having the highest crash rate of all HCLs in the State of Maine. A study was recently completed to address this location
- Exits 19 and 48 are both signalized intersections while Exits 2 and 102 are not signal controlled.

Each high crash intersection is discussed in the following paragraphs.

## 1. Exit 2 NB Off Ramp \& Rodgers Road, Kittery

The location described is the intersection of the Exit 2 NB Off ramp and Rodgers Road (Route 236) in Kittery. Ten of the eleven crashes at this location were rear-end type crashes occurring at the end of the off ramp as traffic yields to the two lanes of through traffic on Route 236. One of the rear-end collisions occurred in slushy road conditions. There is a short three lane weave section immediately following the intersection with no Yield or Stop sign.

Four specific changes can be made at this intersection to improve traffic flow and safety:

1. There are curve arrow signs present on the ramp that are covered by grass, the grass should be trimmed so that the signs are visible.
2. Trees and shrubs in the gore of the intersection should be trimmed and maintained to improve sight distance for merging traffic.
3. Install advanced signs on the ramp warning of the yield ahead.
4. Reconfigure the ramp to approach Route 236 at a sharper angle to increase vehicle visibility for approaching Route 236 traffic.

MaineDOT, the current owner of the ramp and intersection, is undertaking a Pavement Rehabilitation project for Exit $1,2 \& 3$ Southbound as well as the mainline Interstate Southbound in 2013. These changes are recommended to be undertaken as part of that project or by MaineDOT maintenance forces before the Authority considers purchasing this section of the Interstate.
Total number of crashes: 11, CRF: 2.42

## 2. Exit 19 Ramps, Sanford Road (Route 109/9) \& Transportation Center, Wells

The location is the signalized intersection of the Exit 19 Ramps, Sanford Road and the transportation center entrance in Wells. Eight of the nineteen crashes were rear-end type crashes occurring in the eastbound direction approaching the signal on Sanford Road. The eastbound direction is on a downward grade and six of the eight crashes here occurred during inclement weather conditions. In addition, three rear-end crashes occurred on the southbound signal approach where traffic is exiting the Turnpike. Substantial queues were observed during the field visit and have been known to occur at this location. Other crashes at this location include three other rear-end crashes, three crashes were the driver lost control (two went off of the road), one sideswipe, and one turning movement crash.

This location has been observed to have lengthy queues particularly on the off ramps. Signal retiming and re-striping may improve operations at the intersection and reduce queues on all approaches to the intersection. Improvements for this intersection are suggested in the Central York County Connections Study. Those improvements include creating a double left-turn from the offramps to Route 109. Creating a double left turn will reduce delays on all approaches to the intersection.
Total number of crashes: 19, CRF: 1.09

## 3. Exit 48 Ramps, Riverside Street \& Larrabee Road, Westbrook

The location is the signalized intersection of the Exit 48 Ramps, Riverside Street, and Larrabee Road in Westbrook. Twenty of the fifty-two crashes at this location were sideswipes occurring in the southbound direction on Riverside Street approaching the signal. The lane configuration for this approach (from left to right as driving) is left, left/through, and through/right. It seems that a majority of the sideswipes occur when drivers attempt to make left turns side by side; a number of drivers admitted trying to go straight through the intersection from the left only lane.

Twelve crashes were classified as rear-ends on the westbound leg exiting the Turnpike. The lane configuration on this leg is left-through-through-right. The right turn lane is separated by a small island, which is yield controlled causing traffic to generally travel at higher speeds. Other crashes at this intersection included eleven other rear end/sideswipes, eight turning movement crashes, and one vehicle fire.

There are overhead guide signs located on the southbound Riverside Drive. However, there are no standard regulatory overhead lane use signs at this intersection. It could be beneficial if overhead lane
use signs are added on all legs of the intersection to clarify lane use designations. The number of sideswipe crashes is particularly high for vehicles turning left onto the Turnpike from Riverside Street.

Rear-end crashes are of particular concern on the westbound leg of the intersection which serves traffic exiting the Turnpike. It may be possible to decrease the number of crashes at this location by altering the pavement markings.

It is recommended that the signs and pavement markings of the westbound approach be studied further for possible modifications, and that the Authority coordinate with the local municipalities and the MaineDOT regarding improvements for the other legs of the intersection.
Total number of crashes: 52, CRF: 1.91

## 4. Exit 102 Ramps, Lewiston Road (Route 9/126) \& Service Plaza Entrance, West Gardiner

The node described is the stop controlled 4-way intersection of the Exit 102 Ramps, Lewiston Road (Routes $9 / 126$ ) and the West Gardiner service plaza entrance. Twenty-four of the twenty-five crashes at this location were angle crashes.

Limited sight distance may be the cause for most of these crashes. A signal warrant analysis was completed in February 2012 by HNTB Corporation. A traffic signal warrant was met for this location, in accordance with the guidelines set forth in the MUTCD, ${ }^{17}$ and a signal was recommended in a memorandum addressed to the Authority dated February 21 ${ }^{\text {st }}$, 2012. However, meeting a traffic signal warrant does not in itself justify a signal. A meeting was held with MaineDOT. During that meeting, MaineDOT recommended changes to the pavement markings, including re-positioning the stop bars, as a method to improve the safety at this location. As a result, the Authority has implemented the pavement marking recommendations.
Total number of crashes: 25, CRF $^{18}: 19.91$
The detailed collision diagrams for each of these locations can be found in Appendix G. These diagrams provide extensive details concerning each crash that occurs at these high crash locations.

[^14]
## 8 SAFETY AND SPEED EVALUATION - MILE 80 TO 102

HNTB reviewed clear zones, guardrail end treatments, and median openings from the Maine Turnpike Exit 80 in Lewiston to Exit 102 in Gardiner, northbound and southbound. The purpose of the review was to compare the impact on the above noted features of increasing the design speed from 65 mph to 75 mph . The design guidelines used for this review are the AASHTO's, A Policy on Geometric Design of Highways and Streets, $6^{\text {th }}$ Edition, 2011, (referred to as the Green Book) and the Roadside Design Guide, $4^{\text {th }}$ Edition, 2011 (referred to as RDG). This analysis did not include a review of the horizontal and vertical alignment, and acceleration and deceleration lanes.

Clear Zone - A clear zone is the unobstructed, traversable area provided beyond the edge of the through traveled way for the recovery of errant vehicles. From the RDG, Table 3-1 reports for an upper limit speed of 65-70 mph a Clear Zone of 30-34' for side slopes of 1:6 and a clear zone of 38-46' for side slopes of 1:5 to 1:4 (including 1:4). Side slopes of 1:3 up to 1:4 are considered traversable but non-recoverable which means that the slope is not included in the clear zone distance. Slopes steeper than 1:3 should be protected. Note 'a' from Table 3-1 states: When a site-specific investigation indicates a high probability of continuing crashes or when such occurrences are indicated by crash history, the designer may provide clear-zone distances greater than the clear zone shown in Table 3-1. Clear zones may be limited to 30 feet for practicality and to provide a consistent roadway template if previous experience with similar projects or design indicates satisfactory performance. Note 'd' from Table 3-1 states: When design speeds are greater than the values provided, the designer may provide clear-zone distance greater than those shown in Table 3-1.

Data obtained from the original construction plans indicates typical side slopes of 1:3 to 1:4. These fore slopes typically terminate in a ditch section or extend to the clearing line. The latest three year crash history, 2009-2011, indicates no high crash locations identified within this section. Based on this information a typical clear zone of 30 ' could be applied to the sections where a $1: 4$ backslope exists and a typical clear zone consisting of a minimum 10' clear recovery area beyond the toe of slope for sections where a 1:3 backslope exists. There are a fair number of locations where these clear zones are not provided and therefore do not meet recommended guidelines for either a 65 or a 75 mph speed limit.

Due to close proximity of the existing roadside ditches and the vegetation line, the existing condition is generally not in conformance with the guidelines for the current speed of 65 mph and will also not be in conformance with a 75 mph design speed.

Guardrail End Treatments - Current MTA practice for new installations of guardrails and end treatments is to comply with the latest MaineDOT policy and the RDG, which is to meet NCHRP 350 TL-3 requirements. The MTA is also routinely modifying existing installations to meet these requirements as part of stand-alone and mainline paving projects. The RDG (and NCHRP 350) do not specify guardrail treatments based on small differences in speed, for example 65 vs 75 mph , but rather are based on a low-speed or a high-speed test level, specifically 31 and 62 mph respectively. The NCHRP does not provide test data for speeds over 62 mph .

The current Maine Turnpike end treatments (FLEAT 350 for single face guardrail and CAT's for Double face Guardrail) are in conformance with the NCHRP 350 TL- 3 crash test criteria. This is based on a speed of 62 mph .

Median openings - Median openings in the guardrail are legally used by authorized vehicles and illegally used by non-authorized vehicles to reverse direction or to access Turnpike facilities located adjacent to the mainline. The illegal use of these openings presents a safety concern to both the illegal user and the mainline motorists. To provide the greatest amount of safety the MTA is currently reviewing and modifying all median openings to ensure adequate sight distance to and from the opening as well as adequate spacing of these openings to serve the needs of emergency and maintenance personnel. The design variables of interest respective to the openings are: width of opening, guardrail terminal ends and their locations, the decision sight distance (DSD) to and from these openings, and the distances from ramps.

The Maine Turnpike is using an opening width of 80 feet to minimize potential of errant vehicles passing through the opening while providing adequate width for emergency and maintenance vehicles to utilize the opening. A CAT-350 guardrail terminal end, which is designed for NCHRP 350 requirements TL-3-, is the typical end treatment for these openings. These are offset such that the guardrail and terminal ends are closest to the roadway on the approach side of the opening. For example the terminal is adjacent to northbound roadway south of the opening and adjacent to the southbound roadway north of the opening. This minimizes the potential of an errant vehicle passing through the opening and striking the terminal end head-on. The use of DSD versus the Stopping Sight Distance (SSD) is based on the desire to allow a driver to perceive the issue then adjust their speed and path to avoid the obstruction rather than stopping. Based on Green Book, Section 8.3.2 Maintenance or emergency crossovers generally should not be located closer than 1500 feet to the end of a speed-change taper of a ramp or to any structure. This is similar to DSDs found in the Green Book Table 3-3, specifically a DSD of 1365 feet for 65 mph and 1545 for 75 mph . For reference the SSDs are $645^{\prime}$ and $820^{\prime}$ for 65 and 75 mph respectively. Based on these guidelines and the MTA's current speed limit, HNTB has recommended a minimum DSD to and from these opening of 1500 feet as well as locating them 1500 feet from structures and interchange ramps.

We have also evaluated the following as it relates to design speed.

Signing - From the Green Book, Section 2.2.8, Speed reduces the visual field, restricts peripheral vision, and limits the time available for drivers to receive and process information. Features related to this are Exits and Exit signing. A typical sign package for an Exit consists of advanced guide signs placed at 2miles, 1 -mile and $1 / 2$-mile intervals prior to the Exit. Increasing the speed limit from 65 to 75 mph could decrease the travel time from the $1 / 2$-mile sign to the exit from 27.7 seconds to 24.0 seconds. Driver perception time, the time it takes an average driver to perceive then initiate a reaction to some piece of information, is typically estimated at 2.5 seconds. Even from the $1 / 2$-mile sign an average driver traveling at the higher speed limit would be able to perceive the upcoming Exit and have ample time, over 21 seconds, to prepare for exiting.

Highway Infrastructure - This section of mainline consists of two two-lane roadways with shoulders and a median separating the northbound from southbound. Underpasses and overpasses carry the standard lane and shoulder widths under and over rivers and other roadways. There are only two
locations in this section that contain something other than the typical roadway; one is the Sabattus Interchange and the other is the West Gardiner Toll Plaza. In both of these cases there exists a typical sign package alerting the driver of what to expect. There are no complex features within this section, for example a weaving section between two closely spaced interchanges, therefore an average driver traveling at the higher speed limit would be able to perceive the upcoming roadway and infrastructure with ample time to adjust accordingly.

Current Free Flow Speeds - Speed data was collected from four count stations on the Turnpike near Exits 80,86 , and 102 , and near mile marker 98 . From this speed data, an $85^{\text {th }}$ percentile free flow speed was calculated. The speed data used to calculate the $85^{\text {th }}$ percentile free flow speed was taken during daylight hours on clear days. Daylight hours from June 10-12 were analyzed for the locations near Exits 80, 86, and 102. Daylight hours from September 11-13 were analyzed for the location near mile marker 98 . Table $7-1$ shows the $85^{\text {th }}$ percentile speeds for the travel lane (right lane) and the passing lane (left lane), for both directions of the Turnpike segments. As can be seen from Table 8-1, free flow speeds near Exits 80 and 86 are pretty close to the speed limit. Generally free flow speeds near Exit 102 are 5 to 10 mph over the 65 mph speed limit. Free flow speeds near mile marker 98 are $10-15 \mathrm{mph}$ over the speed limit. These speeds could reflect a tendency to slow down in the vicinity of an interchange.

Table 8-1 - 85 ${ }^{\text {th }}$ Percentile Speeds (mph) - Mile 80-102

| NB |  |  | SB |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Travel | Passing | Total | Travel | Passing | Total |
| 76.4 | 79.2 | 77.8 | 76.6 | 79.6 | 78.1 |

Summary - The existing condition for clear zones is generally not in conformance with the guidelines for the current speed of 65 mph and will also not be in conformance with a 75 mph design speed. However, no high crash locations have been designated in this stretch of highway over the last three years.

The current Maine Turnpike guardrail end treatments are in conformance with the NCHRP 350 TL-3 crash test criteria. This is based on a speed of 62 mph . There are no crash test criteria for higher speeds.

HNTB has made recommendations for a minimum DSD to and from median openings of 1500 feet as well as locating the median openings 1500 feet from structures and interchange ramps. This distance meets the Green Book recommendation for 65 mph and is close to the Green Book recommendation for 75 mph .

Before a decision is made on maintaining or increasing the speed limit, the horizontal and vertical alignment should be evaluated. However, the preceding evaluation did not find a design criteria and corresponding existing condition that prevents the speed limit from being raised in this section.

## 9 OFF SYSTEM NEEDS

Planned and potential off-system highway improvements and planned commercial/retail developments can have an effect on the safety, operation, and demands of the Turnpike and could accelerate the need to make forecasted improvements identified in previous sections. The Authority is taking a proactive approach in maintaining an open dialog with the communities along the Turnpike corridor to identify proposed projects that could adversely affect various aspects of the Turnpike operations, including intersections adjacent to Turnpike interchanges; toll plazas, ramps, and the Turnpike mainline.

The Authority obtained a list of current traffic movement permits, issued by MaineDOT, for planned developments in the communities along the Turnpike corridor. The Authority also reviewed MaineDOT's State Transportation Improvement Program (STIP), which is a list of federally funded transportation projects that are outside MPO's, for projects that may affect the turnpikes operations. It does not appear any of the proposed projects on the MaineDOT lists will have any significant effect on Turnpike operations.

Additionally, the Authority sent a letter on June $22^{\text {nd }}, 2012$ to communities and Metropolitan Planning Organizations (MPO's) along the Turnpike corridor requesting information regarding existing reports or studies identifying short or long term transportation improvements or problem areas that are adjacent to the Turnpike. The letter also requested copies of land use or zoning plans and any traffic permits for major commercial developments that would need efficient access to the Turnpike.

The Authority received responses from nine communities. The following is a summary of the information received by the communities:

- Auburn
o 2010 version of the City's Comprehensive Plan. No permitted development addressed in the plan
o Comprehensive Plan that states new Turnpike access is a priority.
o Information about continued airport/intermodal facility development. The City believes that it may create increased demand at Exit 75.
- Falmouth
o Pavement and Transportation Management Plan. The following were identified as needs
- Eliminate tolls on the Falmouth Spur.
- Provide an at-grade intersection of the Falmouth Spur and U.S. Route 1.
- Replace the signalized intersection at Exit 53 and Route 26/100 with a roundabout.
- Gray
o The Northbrook Traffic Impact Assessment for Potential Area 3 Development. The report identifies the need for an additional eastbound lane on Routes 4/26A/115/202 between the Route 26A intersection and Exit 63.
- New Gloucester
o Information about the installation of new public water mains in the Upper Village area along Routes 4/100/202 in 2013.
- Portland
o Information about the construction, in two phases, of a Technology Park located off Rand Road on a parcel abutting Exit 47. The City of Portland will construct the public road into the site with utilities along the road. Under the current plan, the full build out of the park, by developers, will consist of seven buildings with total square footage of approximately 120,000 square feet. Construction of the public road and utilities should be completed in 2013.
- Saco
o A 2011 updated Comprehensive Plan.
o Goals that have been updated to reflect the City's desire to have additional Turnpike connections through new interchanges or the reestablishment of old Exit 5 on Route 112.
- Scarborough

0 Recent zoning changes around Exit 42 and along the Haigis Parkway.

- Proposed service station with fuel and restaurant(s) adjacent to Exit 42 on Payne Road.
- New recently approved $15,000-16,000$ square foot office building to be located on the Haigis Parkway.
0 Information regarding the Dunstan Corner intersection project.
- Wells

0 Information regarding possible extension of public water and sanitary sewer from Spencer Drive westerly on Routes $9 / 109$ to the Transportation Center located opposite Exit 19.
o Information regarding the need to widen Routes 9/109 west of Exit 19 to better accommodate the easterly left turn lane into Exit 19.
0 A request to consider an additional interchange in the region to help mitigate traffic congestion along U.S. Route 1 in the Wells, Ogunquit and York region.
o A request to consider creation of a Transportation Center District at the Wells Transportation Center facility to develop mixed-use businesses to serve travelers.

- Westbrook
o Information regarding development of Stroudwater Place.
- Parcel located between Westbrook Arterial and Westbrook Street opposite Larrabee Road.
- Developer needs approval from MaineDOT for access to parcel from Westbrook Arterial which is a Control of Access right of way. The City expects some development to occur within 10-year time period.
o Information regarding development/expansion of existing development along the Larrabee Road Corridor between Exit 48 and Westbrook Arterial.

Based on the above responses, the following are possible impacts to the Turnpike that may require operational improvement considerations to accommodate potential traffic increases.

Auburn - The Authority recently evaluated Exit 75, the roadway system and intersections around Exit 75. Expected growth from the airport and industrial parks were included in the evaluation. The recommendations from that study included improvements to two local intersections. The
recommendations were found to provide the most benefit for the cost; have the least impact to parcels that have potential for future economic development; were permittable; and addressed all of the transportation deficiencies identified under the future no-build alternative. Based on the results of this study, MaineDOT is currently developing plans and specifications to implement these improvements. The Authority also recently completed the lengthening of the northbound acceleration ramp and is currently lengthening the southbound acceleration ramp at Exit 75. No additional improvements are planned in the foreseeable future.

Falmouth - There are currently no identified operational or safety deficiencies at locations in Falmouth, with the exception of the Exit 53 ramps between the toll plaza and the adjacent intersection with Route $26 / 100$. HNTB Corporation recommends monitoring this ramp in future years to see if it continues to be classified as a high crash location and if a pattern develops.

Gray - The consideration of an additional eastbound travel lane is currently being evaluated as a part of the Gray Interchange Study.

New Gloucester - The planned water line installation in the Upper Village area may attract development but is not expected to impact Turnpike operations over the next 30 years.

Portland - It is assumed that additional traffic generated by the proposed Technology Park will increase traffic at Exit 47 thereby increasing congestion on the Turnpike through the Portland region. That could accelerate the need for adding capacity along the mainline of the Turnpike in the Portland area.

Saco -The communities of Saco and Scarborough are considering a study that will evaluate traffic congestion in their respective communities.

Scarborough - Proposed developments along the Haigis Parkway resulting from recent zoning changes will likely increase traffic volumes at Exit 42 thereby increasing congestion on the Turnpike north and south of Exit 42. That could reduce the timeframe when this section of the Turnpike is forecasted to reach a failing LOS and may require additional capacity to be added at the Scarborough toll plaza.

Wells - The Authority currently has no plans for evaluating any improvements to Routes 9/109 in the vicinity of Exit 19. However, this area is a high crash location. Some improvements to the intersection and ramps are suggested to improve safety at this location.

Currently, the Authority is not engaged in any studies regarding the need for an additional interchange to serve the Wells, Ogunquit and York communities.

The planned water line extension on Routes $9 / 109$ may attract development but is not expected to impact Turnpike operations over the next 30 years.

Westbrook - The proposed Stroudwater Place Development (a 61 acre site with a proposed 1.7 million square feet of mixed use development) located in the vicinity of Exit 47 coupled with the Portland Technology Park development mentioned above will adversely affect capacity of the

Turnpike. Traffic from these developments could accelerate the need for adding capacity along the mainline of the Turnpike in the Portland area. Proposed development/expansion of existing development along the Larrabee Road corridor could increase traffic volumes at both Exits 47 and 48 that could further increase congestion along the Turnpike through the Portland Region.

Summary - the effects from traffic generated by the proposed and permitted developments in Portland, Scarborough and Westbrook adjacent to Exits 42, 47 and 48 could adversely impact the timelines for which capacity improvements will need to be made in those areas.

## 10 COST ANALYSIS

Previous sections of this study identified a timeline when the Turnpike mainline segments, ramps, and toll plazas would reach capacity. The timeline for capacity improvements could be hastened depending on the impacts of commercial developments identified in Portland, Westbrook, and Scarborough, as well as the results of other ongoing studies, especially the Gorham East-West Corridor Feasibility Study.

As a result of the forecasted capacity needs, widening projects and cost for those projects were developed for the timelines established. When computing future costs for construction a few key assumptions were made:

- Construction costs and schedules are for the year that a segment, ramp or merge/diverge area reaches a LOS F.
- The cost to add a single lane to either a mainline or ramp in the year 2012 is $\$ 2,350,000 / \mathrm{mile}$. Major items for adding a lane considered include clearing, pavement/gravel template, removing the existing shoulder, guardrail, stone ditch protection, loam, pavement markings, mobilization, median guardrail, ROW fence, traffic maintenance, common excavation, common borrow, and rock excavation. The total was then increased by a factor of $15 \%$ to account for smaller, miscellaneous costs involved with this type of large scale project.
- Ramp widening will add a 12 ' lane and a 10 ' shoulder.
- Ramps being widened to 2 lanes are to be lengthened 400' beyond their current length.
- The mainline widening will add 24 ' to the existing roadway.
- A conservative $3 \%$ inflation factor per year is implemented when forecasting future costs.
- All bridges South of Mile 44 have been designed to handle a mainline widening to four lanes and are not being considered for any replacement or repairs in this study.

Construction of each improvement would ideally begin during the year that an area reaches a failing Level of Service (LOS F). These years have been calculated for each merge/diverge area, ramp and mainline segment and are presented in the tables within Section 3. The following cost calculations are based on the year that a given area is expected to reach LOS F. The construction schedule and forecasted costs are adjusted further to help reduce construction costs by grouping similar projects in adjoining locations in the same year. Table 10-1 displays proposed improvements which would alleviate the inadequate levels of service expected to be produced by forecasted volumes.

In the right hand column of Table 10-1, the total estimated costs of each improvement necessary to create a passing level of service is displayed. It is important to remember that these costs are summarized for the year during which construction is recommended to begin. The actual construction of various improvements may be spread out over more than one construction season.

In general, mainline sections for the northbound travel direction reach capacity several years before the southbound travel direction due to higher design hour volumes. The actual years that directional mainline widening is forecasted is shown in Table 10-1. However, the northbound and southbound sections would likely be permitted and constructed at the same time at a time when both sections reach capacity.

Table 10-1 - Forecasted Problems and Cost of Improvements

| Year of Failure (LOS F) | Exit \#/ Segment mileage | Location | Reason for failure | Necessary Improvement | Length of Improvement Area (miles) | Cost of Improvement in 2005 | Forecasted Cost of Improvement for Year in Question | Necessary <br> Bridge Expansion? | Cost of Bridges in 20012 | Forecasted Cost of Bridges for Year in Question | Total Forecasted Cost |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 2017 | 0-2 | NB Mainline | Mainline Capacity | Mainline Widening ${ }^{1}$ | 1.1 | \$ 2,585,000 | \$ 2,966,700 | $\mathrm{NO}^{2}$ |  |  | \$ 2,996,700 |

| 2035 | 2-7 | SB Mainline | Mainline Capacity | Mainline Widening | 5.7 | \$ 13,400,000 | \$ 26,446,000 | NO |  |  | \$ 26,446,000 |
| 2037 | 44-47 | SB Mainline | Mainline Capacity | Mainline Widening | 3 | \$ 7,050,000 | \$ 14,761,000 | YES ${ }^{3}$ | \$ 3,400,000 | \$ 7,118,800 | \$21,880,000 |
| 2038 | 36 | SB On Ramp | Merge Area Capacity | Ramp Widening | 0.56 | \$ 1,316,000 | \$ 2,838,100 | NO |  |  | \$ 2,838,100 |

 not widened). Because of capacity issues, coordination with the New Hampshire Department of Transportation will be needed in the near future.
The widening of the bridge over the Piscanaua River is on tinduded in this analysis.
${ }^{3}$ Bridges from MM $44-48$ may need work sooner if part of the bridge program.

## 11 RECOMMENDATIONS/SUMMARY OF FINDINGS

This study assessed operating conditions of all interchanges, mainline sections, ramps, and toll plazas on the Turnpike between Kittery and Augusta. This study also included an assessment of high crash locations for all mainline sections, ramps, toll plazas, and intersections of local roads with Turnpike ramps. In addition, this study also included the following information:

- An analysis of Park and Ride lots adjacent to the Turnpike
- An evaluation of speeds from Exits 80-102
- Information from municipalities adjacent to the Turnpike regarding short or long term transportation improvements or problem areas

## CAPACITY IMPROVEMENTS

Capacity improvements, presented in Table 11-1, are based on the results of capacity analyses performed. Included in Table 11-1are possible future improvements, an approximate time table of when the improvements will become necessary, and an estimate of the forecasted construction costs. HNTB Corporation has adjusted the construction schedule and costs previously presented to create an optimal timeline which will minimize construction costs by grouping similar projects in adjacent areas. The costs have been forecasted to the year that construction is proposed to begin. To summarize for budgeting purposes Table 11-1 combines the cost of all projects proposed to begin in the same year.

Table 11-1 - Cost of Proposed Improvements by Year

| Year | Total Forecasted <br> Cost | Location of Proposed Improvement |
| :--- | :--- | :--- |
| $2017^{1}$ | $\$ 2,996,700$ | NH State Line to Kittery Exit 2 - NB Mainline |
| 2018 | $\$ 3,617,500$ | Exit 36 Saco - Toll Lanes and NB On-ramp |
| 2021 | $\$ 2,423,000$ | Exit 36 Saco - NB Off Ramp |
| $2022^{1}$ | $\$ 7,962,600$ | NH State Line to Kittery Exit 2 - SB Mainline and Exit 2 SB-On-ramp |
| 2023 | $\$ 1,366,200$ | Exit 44 I-295 Scarborough SB On-Ramp |
| 2025 | $\$ 16,058,000$ | Jetport to Westbrook - NB Mainline |
| 2030 | $\$ 3,360,000$ | Exit 36 Saco - SB Off Ramp |
| 2031 | $\$ 25,062,900$ | Kittery Exit 2 to York - NB Mainline and Biddeford NB on-ramp |
| 2034 | $\$ 50,366,500$ | I-295 Scarborough to Jetport - NB Mainline <br> and Exit 32 Biddeford - SB off-ramp |
| 2035 | $\$ 26,446,000$ | Kittery Exit 2 to York - SB Mainline |
| 2037 | $\$ 21,880,000$ | I-295 Scarborough to Rand Rd - SB Mainline |
| 2038 | $\$ 2,838,100$ | Exit 36 Saco - SB On Ramp |

${ }^{1}$ Traffic between Exits 0-7 is constrained by the Piscataqua River Bridge. Peak hour northbound traffic will not reach forecasted levels due to the traffic capacity constraint of the bridge. Conversely, peak hour traffic southbound will not benefit from widening if the capacity of the bridge is less than the mainline (i.e. if the bridge is not widened). Because of capacity issues, coordination with the New Hampshire Department of Transportation will be needed in the near future.

Three toll plazas (Biddeford, Scarborough, and Gray) are operating at over 75\% capacity and lie in close proximity to a local signalized intersection. Operations at these plazas should be monitored to ensure that the toll plaza operations do not interfere with the flow of traffic on local roads. This will be particularly important at Biddeford and Gray, because these plazas will be operating at $80-90 \%$
capacity during peak periods. Periodic surges at these plazas could result in temporary interference with the local roads.

## HIGH CRASH LOCATIONS

Improvements that could be considered to improve high crash locations are the following:

- Advanced overhead signing for the York interchange on the southbound approach to the interchange.
- Modifying the acceleration lane at Wells to I-95 northbound from a taper to a parallel ramp
- A pavement sensor in the northbound lanes just north of the Wells interchange
- A pavement sensor in the southbound lanes north of Mayall Road in New Gloucester
- Deer crossing warning signs at Mile 71 north of Shaker Hill
- Sonic Nap Alert Patterns (SNAPS) on the shoulder of the southbound off-ramp in Wells
- Changes to guide signs at Exit 25 southbound off-ramp
- Overhead lane use signs at Exit 48 off-ramps right after the toll plaza

## PARK AND RIDE LOTS

All of the park and ride lots owned by the Authority have been utilized at a rate of less than $75 \%$ of available capacity for every year of the last three years with exceptions of the lots at Gray and Lewiston. The Gray Interchange is being studied. Possible relocation of the park and ride lot is part of that study. A new interchange in Lewiston is currently in the 30 -year plan. Due to the re-design of the Exit 80 interchange, a larger, single, relocated, park and ride lot is being built and is scheduled to be open late fall 2012.

## SPEED EVALUATION

Before a decision is made on maintaining or increasing the speed limit, the horizontal and vertical alignment should be evaluated. However, the evaluation did not find a design criteria and corresponding existing condition that prevents the speed limit from being raised in the section of roadway from Exit 80-102.

## OFF SYSTEM NEEDS

The Authority took a proactive approach to identify proposed projects that could adversely affect various aspects of Turnpike operations. The Authority obtained a list of current traffic movement permits, issued by MaineDOT for planned developments in the communities along the Turnpike corridor. The Authority also reviewed MaineDOT's State Transportation Improvement Program (STIP), for projects that may affect the turnpikes operations. Additionally, the Authority sent a letter to communities and Metropolitan Planning Organizations (MPO's) along the Turnpike corridor requesting information regarding existing reports or studies identifying short or long term transportation improvements or problem areas that are adjacent to the Turnpike. The following information received may impact the timeline for capacity improvements.

- Additional traffic generated by the proposed Technology Park will impact Turnpike traffic at and near Exit 47
- The proposed Stroudwater Place Development will also impact Turnpike traffic at and near Exit 47
- The cities of Saco and Scarborough are considering a study that will evaluate traffic congestion in their respective communities.
- Proposed developments along the Haigis Parkway will likely increase traffic volumes at or near Exit 42

A point of considerable interest, which arose during the research for this study, is the possible need for improvements that would involve the need for advanced planning with MaineDOT and local municipalities. These include, but are not limited to:

- Capacity needs on the Piscataqua River Bridge (also includes New Hampshire Department of Transportation)
- Study of traffic congestion in Saco
- Possible improvements to intersections adjacent to the Turnpike in Kittery, Wells, Westbrook, and Biddeford

## OTHER STUDIES

Outside of the course of this study, specific projects and issues have been identified that are being analyzed separately. They include the following studies:

- Relocation of the York Toll Plaza (MM 7.3)
- Improvements to the Gray Interchange (Exit 63)
- Improvements to the Lewiston Interchange (Exit 80)
- Improvements to the Gardiner I-295 Toll Plaza (MM 103.0)
- Exit 103/Route 126 intersection improvements
- Gorham East-West Corridor Feasibility Study
- Central York County Connections Study

The results of these studies could influence the timeline for capacity improvements on the Turnpike.

# Appendix A Level of Service Description 

DEFINITIONS AND CONCEPTS

Table 1-1. Types of Facilities

| FACILITY | CHAPTER |
| :---: | :---: |
| Uninterrupted Flow Facilities |  |
| Freeways |  |
| Basic freoway segments | 3 |
| Weaving areas. | 4 |

| Bicyales | 14 |

essary to examine points of fixed interruption as well as uninterrupted flow segments.

Pedestrian and transit flows are generally considered to be interrupted. Uninterrupted flow can exist under certain circumstances, such as in a long busway without stops or a long pedestrian corridor.

## CAPACITY AND LEVEL-OF-SERVICE CONCEPTS

A principal objective of capacity analysis is the estimation of the maximum amount of traffic that can be accommodated by a given facility. Capacity analysis would, however, be of limited utility if this were its only focus. Traffic facilities generally operate poorly at or near capacity, and facilities are rarely designed or planned to operate in this range. Capacity analysis is also intended to estimate the maximum amount of traffic that can be accommodated by a facility while maintaining prescribed operational qualities.

Capacity analysis is, therefore, a set of procedures used to estimate the traffic-carrying ability of facilities over a range of defined operational conditions. It provides tools for the analysis and improvernent of existing facilities, and for the planning and design of future facilities.

The definition of operational criteria is accomplished using levels of service. Ranges of operating conditions are defined for each type of facility, and are related to amounts of traffic that can be accommodated at each level.

The following sections present and define the two principal concepts of this manual: capactiy and level of service.

## Capacity

In general, the capacity of a facility is defined as the maximum hourly rate at which persons or vehicles can reasonably be expected to traverse a point or uniform section of a lane or roadway during a given time period under prevailing roadway, traffic, and control conditions.

The time period used in most capacity analysis is $15-\mathrm{min}$ which is considered to be the shortest interval during which stable flow exists.

Capacity is defined for prevailing roadway, traffic, and control conditions, which should be reasonably uniform for any section of facility analyzed. Any change in the prevailing conditions will result in a change in the capacity of the facility. The definition of capacity assumes that good weather and pavement conditions exist.

1. Roadway conditions-Roadway conditions refer to the geometric characteristics of the street or highway, including: the type of facility and its development environment, the number of lanes (by direction), lane and shoulder widths, lateral clearances, design speed, and horizontal and vertical alignments.
2. Traffic conditions-Traffic conditions refer to the characteristics of the traffic stream using the facility. This is defined by the distribution of vehicle types in the traffic stream, the amount and distribution of traffic in available lanes of a facility, and the directional distribution of traffic.
3. Control conditions-Control conditions refer to the types and specific design of control devices and traffic regulations present on a given facility. The location, type, and timing of traffic signals are critical control conditions affecting capacity. Other important controls include sTor and YIELD signs, lane use restrictions, turn restrictions, and similar measures.

These and other factors affecting capacity are discussed in greater detail in a subsequent section of this chapter.

It is also important to note that capacity refers to a rate of vehiculat or person flow during a specified period of interest, which is most often a peak $15 \cdot \mathrm{~min}$. period. This recognizes the potential for substantial variations in flow during an hour, and focuses analysis on intervals of maximum flow.

## Lovaly of Service

The concept of levels of service is defined as a qualitative measure describing operational conditions within a traffic stream, and their perception by motorists and/or patsengers. A level-of-service definition generally describes these conditions in terms of such factors as speed and travel time, freedom to maneuver, traffic interruptions, comfort and convenience, and safety.

Six levels of service are defined for each type of facility for which analysis procedures are available. They are given letter designations, from $A$ to $F$, with level-of-service $A$ representing the best operating conditions and level-of-service $F$ the worst.

1. Level-of-service deffitions-In general, the various levels of service are defined as follows for uninterrupted flow facilitics:

- Level-of-service $A$ represents free flow. Individual users are virtually unaffected by the presence of others in the traffic stream. Freedom to select desired speeds and to maneuver within the traffic stream is extremely high. The general level of comfort and convenience provided to the motorist, passengef, or pedestrian is excellent.
- Level-of-service $B$ is in the range of stable flow, but the presence of other users in the traffic stream begins to be noticeable. Freedom to select desired speeds is relatively unaffected, but there is a slight decline in the freedom to maneuver within the traffic stream from LOS A. The level of comfort and convenience provided is somewhat less than at $\operatorname{LOS} A$, because the presence of others in the traffic stream begins to affect individual behavior.
- Level-of-service $C$ is in the range of stable flow, but marks the beginning of the range of flow in which the operation of individual users becomes significantly affected by interactions with others in the traffic stream. The selection of speed is now affected by the presence of others, and maneuvering within the traffic stream requires substantial vigilance on the part of the user. The general level of comfort and convenience declines noticeably at this level.
- Level-of-service $D$ represents high-density, but stable, flow. Speed and freedom to maneuver are severely restricted, and the driver or pedestrian experiences a generally poor level of comfort and convenience. Small increases in traffic flow will generally cause operational problems at this level.
- Level-of-service $E$ represents operating conditions at or near the capacity level. All speeds are reduced to a low, but relatively uniform value. Freedom to maneuver within the traffic stream is extremely difficult, end it is generally accomplished by foreing a vehicle or pedestrian to "give way" to accommodate such mancuvers. Comfort and convenience levels are extremely poor. and driver or pedestrian frustration is generally high. Operations at this level are usually unstable, because small increases in flow or minor perturbations within the traffic stream will cause breakdowns.
- Level-of-service $F$ is used to define forced or breakdown flow. This condition exists wherever the amount of traffic approaching a point exceeds the amount which can traverse the point. Queues form behind such locations. Operations within the queue are characterized by stop-and-go waves, and they are extremely unstable. Vehicles may progress at reasonable speeds for several hundred feet or more, then be required to stop in a cyclic fashion. Level-of-service $F$ is used to describe the operating conditions within the queus, as well as the point of the breakdown. It should be noted, however, that in many cases operating conditions of vehicles or pedestrians discharged from the queue may be quite good. Nevertheless, it is the point at which arrival flow exceeds discharge flow which causes the queue to form, and level-of-service $F$ is an appropriate desig. nation for such points.
These definitions are general and conceptual in nature, and they apply primarily to uninterrupted flow. Levels of service for interrupted flow facilities vary widely in terms of both the user's perception of service quality and the operational variables used to describe them. Each chapter of the manual contains more detailed descriptions of the levels of service as defined for each facility type.

2. Service flow rates - The procedures of this manual attempt to establish or predict the maximum rate of flow which can be accommodated by various facilities at each level of service. except level-of-service $F$, for which flows are unstable. Thus, each facility has five service flow rates, one for each level of service (A through $E$ ), defined as follows.

The service flow rate is the maximum hourly rate at which persons or vehicles can reasonably be expected to traverse a point or uniform section of a lane or roadway during a given time period under prevailing roadway, traffic, and control conditions while maintaining a designated level of service. As to capacity, the service flow rate is generally taken for a 15 -min time period.

Note that service flow rates are discrete values, while the
levels of service represent a range of conditions. Because the service flow rates are defined as maximums for each level of service, they effectively define flow boundaries between the various levels of service.
3. Measures of effecriveness-For each type of facility, levels of service are defined based on one or more operational parameters which best describe operating quality for the subject facility type. While the concept of level of service attempts to address a wide range of operating conditions, limitations on data collection and availability make it impractical to treat the full range of operational parameters for every type of facility. The parameters selected to define levels of service for each facility type are called "measures of effectiveness," and represent those available measures that best deseribe the quality of operation on the subject facility type. Tabie 1-2 gives the measures of effectiveness used to define levels of service for each facility type.
Each level of service represents a range of conditions, as defined by a range in the parameter(s) given in Table 1-2. Thus, a level of service is not a discrete condition, but rather a range of conditions for which boundaries are established.

Table 1-2. Mrasures of Empetiveness for Level of Service Definition

| TYPE OF FACLITIT | MEASURE OF EFFECTIVENESS |
| :---: | :---: |
| Freeways |  |
| Basic freeway segments . . . . . . | Density ( $\mathrm{pc} / \mathrm{mi} / \mathrm{ln}$ ) |
| Weaving areas. . . . . . . . . . . . | Average travel speed (mph) |
| Ramp junctions . . . . . . . . . . | Flow rates (peph) |
| Multilane Highways. . . . . . . . . . . | Density ( $\mathrm{pc} / \mathrm{mi} / \mathrm{ln}$ ) |
| Two-Lane Highways . . . . . . . . . | Porcent time delay (\%) <br> Average travel speed (mph) |
| Signalized lntersections . . . . . . . . | Average individual stopped delay ( $\mathrm{sec} / \mathrm{veh}$ ) |
| Unsignalized Intersections....... | Reserve capatity (paph) |
| Arterials, ....... | Average travel speed (mph) |
| Transit | Load factor (perts seat) |
| Pedestrians | Space (sq ft/ped) |

## gasic principles of traffic flow

## Traffle Flow Measures

The operational state of any given traffic stream is defined by three primary measures:

1. Speed.
2. Volume and /or rate of flow.
3. Density.
4. Speed is defined as a rate of motion expressed as distance per unit time, generally as miles per hour (mph) or kilometers per hour ( $\mathrm{km} / \mathrm{h}$ ). In characterizing the speed of a traffic stream, some representative value must be used, as there is generally a broad distribution of individual speeds that may be observed in the traffic stream. For the purposes of this manual, the speed measure used is average travel speed. This measure is used because it is easily computed from observation of individual vehicles within the traffic stream, and because it is the mos: statistically relevant measure in relationships with other varia-

## Appendix B Factors \& Truck Percentages

DRIVER POPULATION ADJUSTMENT FACTOR REASONING:

- If most of the 30 busiest hours were related to weekend traffic (Friday PM, Saturday, Sunday, or holidays), then a factor of 0.85 was used.
- If the busiest hours were evenly split between weekdays and weekends a factor of 0.90 was used.
- If the busiest hours were not closely correlated to weekend traffic at all a factor of 1.00 was used.

## Appendix C Non-Typical Diverge Calculations

Non-Typical Diverge Case: Exit 44

See pg. 13-27 of Highway Capacity Manual
Equation 13-27:

$$
\mathrm{Dmd}=.0175^{*}(\mathrm{Vf} / \mathrm{N})
$$

Ramps $30^{\text {th }}$ Hour Analysis

| INPUT | OUTPUT |
| :--- | :--- |

Table D-1 shows the 'worst case scenario volumes'. Volumes were predicted using the annual growth rate of $1.1 \%$ and were calculated using the compounding interest formula:

$$
\mathrm{Vf}=\mathrm{V}_{c}^{\star}(1+\mathrm{g})^{\wedge} \mathrm{T}
$$

Where:

- $V f=F o r e c a s t e d ~ V o l u m e ~$
- Vc=Current Volume (2011 data)
- $\mathrm{g}=$ annual growth rate for segment in question (.011)
- $\mathrm{T}=$ Year in question ( 10,20 , or 30 years from 2011)

Table D-2 shows the future LOS values for each merge area based on the predicted volumes.

Table D-3 shows the 'worst case scenario volumes'. Volumes were predicted using the annual growth rate of $1.1 \%$ and were calculated using the compounding interest formula:

$$
\mathrm{V}_{\mathrm{f}}=\mathrm{V}_{\mathrm{c}}{ }^{\star}(1+\mathrm{g})^{\wedge} \mathrm{T}
$$

Where:

- $\mathrm{V}_{\mathrm{f}}=$ Forecasted Volume
- $\mathrm{V}_{\mathrm{c}}=$ Current Volume (2011 data)
- $g=$ annual growth rate for segment in question (e.g. 0.011 , or $1.1 \%$ )
- $\mathrm{T}=$ Year in question ( 10,20 , or 30 years from 2011)

Table D-4 shows the future LOS values for each merge area based on the predicted volumes.

[^0]:    ${ }^{1}$ Capacity improvements to the Gray interchange and subsequently the Gray Toll Plaza are currently being studied separately.

[^1]:    ${ }^{2}$ Transportation Research Board. Highway Capacity Manual, Washington, D.C.: 2010

[^2]:    ${ }^{3} 1,650$ vehicles per lane per hour is the observed practical capacity of Turnpike ramps.

[^3]:    ${ }^{4}$ As stated in footnote $3,1,650$ vehicles per lane per hour is the observed practical capacity of Turnpike ramps.

[^4]:    ${ }^{5}$ Additionally, the Authority in coordination with MaineDOT count all of the Park and Ride lots in the State of Maine biannually

[^5]:    ${ }^{6}$ Gray Interchange is also currently being studied which may result in moving the southbound ramps and toll plaza to the west side of the Turnpike.

[^6]:    ${ }^{7}$ This capacity is only relevant at New Gloucester. Once construction is complete, the facility will operate with 1 ORT lane and 3 cash lanes in each direction.

[^7]:    ${ }^{8}$ MaineDOT reviews all traffic permits for development in Maine. MaineDOT coordinates with the Authority regarding developments which could potentially impact the Turnpike.
    ${ }^{9}$ Toll plazas in this range could be problematic particularly if adjacent to a traffic signal. Further study would be needed to determine effects of traffic signals on toll plaza operations.
    ${ }^{10}$ The anticipated length of the peak-hour queues would need to be determined by traffic simulation modeling, using a program such as Vissim.

[^8]:    | $101 \%$ |
    | :--- |
    | $99 \%$ |

    Plaza is operating over capacity
    Plaza is operating at $90-100 \%$ capacity

[^9]:    ${ }^{11}$ If the actual peak-hour E-ZPass usage reaches beyond the assumed penetration limit of $80 \%$, then the expected volume of cash-paying traffic would be cut. If the share of E-ZPass usage continued to grow at a rate of about $1 \%$ per year beyond 2018, then the plaza would be able to operate fairly efficiently with 1 cash lane and $2 \mathrm{E}-\mathrm{ZPass}$ lanes in the future.
    ${ }^{12}$ If the possibility of traffic issues is of concern to the Authority, a more detailed simulation model could be developed in Vissim that could quantify the problem and help identify mitigation measures.

[^10]:    ${ }^{13}$ The cost for the toll lane is discussed in Section 10.

[^11]:    ${ }^{14}$ This location is adjacent to the northern limits of the Turnpike.

[^13]:    ${ }^{16}$ Critical rate factors are computed differently for nodes and elements. The calculation for a critical rate factor for an element includes the length of the element. Nodes essentially have no length. Therefore, the critical rate factors for nodes are not necessarily comparable to the critical rate factors for elements.

    ${ }^{18}$ The CRF has been updated by MaineDOT since publication of the February memorandum.
